Forecast for Germany: Significantly gloomier growth outlook – inflation decreases to 2% The German economy is not only struggling with persistent economic headwinds, but is also having to adapt to changing structural conditions. This is affecting the industrial sector in particular, putting a strain on its export business and investments. The labour market, too, is now responding noticeably to the protracted weakness of economic activity. This is dampening private consumption. Against this backdrop, the German economy is set to stagnate in the winter half-year 2024-25 and only begins to make a slow recovery over the course of 2025. Exports then gradually benefit from the growing sales markets, albeit to a lesser extent than used to be the case. After some delay, business investment also goes back up on the back of rising capacity utilisation and lower financing costs. Private consumption rises consistently, but is initially noticeably slowed by a temporary weakening of the labour market and a significant decline in wage growth.

Calendar-adjusted real GDP falls again slightly in 2024, by 0.2%, then grows by 0.2% in 2025, 0.8% in 2026 and 0.9% in 2027. The growth outlook is thus revised sharply downwards relative to the June 2024 Forecast for Germany over the entire forecast horizon. This is primarily due to the more persistent weakness in the industrial sector, which is, in addition, largely considered to be structural now, and the consequently significantly gloomier outlook for exports and business investment. Private consumption is also less dynamic, no longer acting as an independent driver of the expected recovery.

In spite of subdued economic activity, the inflation rate remains elevated in 2025, falling only slightly from 2.5 % this year to 2.4 % (as measured by the HICP). This is due to the temporarily steeper rise in food prices and the only slowly abating increase in the price of services. In the years that follow, however, the inflation rate in Germany gradually returns to 2 %, because the effects of previous monetary policy tightening linger and price pressures from labour costs decrease. Compared with the June Forecast, the inflation outlook has been revised downwards somewhat, mainly due to lower energy prices and lower wage growth.

The government deficit ratio decreases slightly, from 2.6 % in 2023 to 2.4 % in 2027. Although the expiry of measures put in place to address the energy crisis is providing some relief, other expenditure, such as social security, interest and defence spending, is climbing strongly. The debt ratio falls to 61.7 % in 2027 (2023: 62.9 %).

Current uncertainty factors influencing the Forecast concern, in particular, increasing protectionism, geopolitical conflicts, the impact of structural change and the orientation of future fiscal and economic policy following the Bundestag elections. All in all, as things now stand, risks to economic growth are predominantly tilted to the downside and risks to inflation to the upside.

1 Macroeconomic outlook

1.1 The German economy is emerging only slowly from stagnation

Hopes back in the spring of a slowly strengthening recovery of the German economy were not realised. Instead of expanding markedly, real GDP declined somewhat in the summer half-year in seasonally adjusted terms. ¹⁾ Despite growing sales markets, exports contracted sharply. The impact of the German economy's reduced competitiveness was thus more strongly felt than expected. Against this backdrop, compounded by declining output and a very low level of capacity utilisation in the industrial sector, firms dialled back their investment more substantially than anticipated. Housing investment also fell more sharply than predicted. Private consumption growth ultimately fell significantly short of expectations as well. Persistently weak economic activity, coupled with a more unfavourable development of the labour market, likely contributed to this.

It is becoming increasingly apparent that the German economy is struggling not only with persistent economic headwinds, but also with considerable structural problems. It is under great pressure to adapt due to changing structural conditions both at home and abroad. This is mainly a problem for the export-oriented industrial sector. Domestically producing industrial firms must adjust, in particular, to the longer-term effects of the energy price shock triggered by Russia's war of aggression against Ukraine, ²⁾ the requirements of the green transition to a carbon-neutral economy ³⁾ and the consequences of demographic change. ⁴⁾ Demanding regulatory requirements for

¹ Seasonal adjustment here and in the remainder of this text also includes adjustment for calendar variations, provided they can be verified and quantified. In June's Forecast for Germany, cumulative GDP growth of 0.5 % was expected for the second and third quarters of 2024 (see Deutsche Bundesbank (2024a)). In actual fact, GDP contracted by 0.3 % in the second quarter and rose by only 0.1 % in the third quarter.

² See Deutsche Bundesbank (2022a).

³ This applies in particular to the motor vehicle industry; for more information, see Deutsche Bundesbank (2024b), Recent developments in Germany's automotive industry, supplementary information in The German economy.

⁴ See Deutsche Bundesbank (2017).

enterprises ⁵⁾ and uncertainty surrounding the economic policy conditions are also burdens here. ⁶⁾ In addition, German firms are being confronted with increasing protectionist tendencies and growing competition from emerging markets. China, in particular, has gained considerable ground in the automotive and chemical industries and mechanical engineering – sectors which are particularly integral to German industry – as well as distinct market shares. ⁷⁾

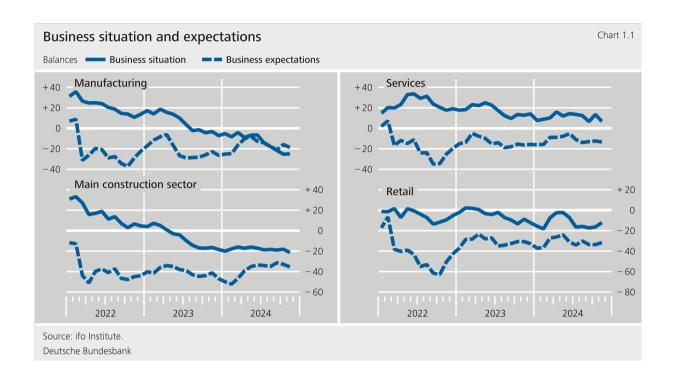

In the fourth quarter of 2024 and the first quarter of 2025, too, the German economy is unlikely to emerge from its stagnation. 8) The improved sentiment among firms back in the spring has deteriorated markedly again in recent months. Particularly in the industrial sector, business conditions deteriorated, according to ifo Institute, and firms are more pessimistic about their short-term prospects. Industrial output and exports are therefore likely to decline somewhat further. Business investment will also probably continue to decrease. The construction sector could slowly stabilise at a low level, but housing investment, in particular, will probably be weaker again at first. Although service providers are likely to provide some support in the short term, their business, too, weakened somewhat, according to surveys conducted by S&P Global and ifo Institute. Private consumption could at least provide limited impetus. Overall, however, economic output is likely to stagnate in the current winter half-year. Economic data for October, which were published after the Forecast was finalised, support this assessment and indicate a weak start to the fourth guarter. For instance, production in the industrial and construction sectors was, respectively, noticeably and slightly below third-quarter levels, and real retail sales did not quite manage to maintain their Q3 level either.

⁵ According to ifo Institute(CESifo 2024), strict regulation and excessive bureaucracy are the main factors dampening investment by German enterprises.

⁶ See Deutsche Bundesbank (2024c).

⁷ See Deutsche Bundesbank (2024b).

⁸ The Bundesbank finalised this Forecast for Germany on 27 November 2024. It was incorporated into the projections for the euro area published by the European Central Bank(ECB) on 12 December 2024.

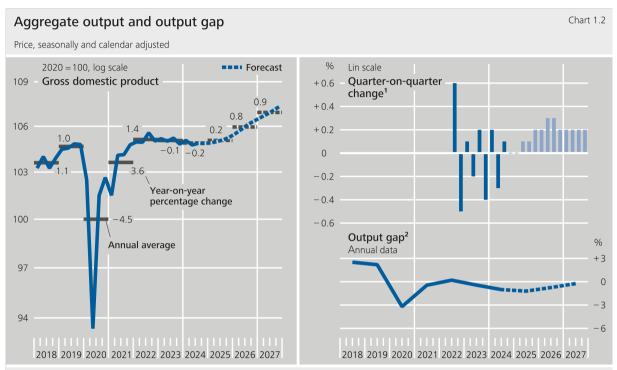

The German economy will only slowly emerge from stagnation over the remainder of 2025. In particular, continuously rising and solidifying foreign demand suggests that the German economy will slowly return to a moderate expansion path over the course of next year. ⁹⁾ The German export industry gradually begins to benefit from the increase in foreign demand, albeit to a lesser extent than was once the case due to strong competitive pressure. Exports thus gradually regain their footing. Private investment, by contrast, continues to decline for the time being. Private consumption will initially grow only weakly: contrary to expectations in previous forecasts, it is no longer a strong, independent driver of the recovery. This is mainly due to the fact that real disposable income is significantly weaker in view of a gloomier labour market outlook and lower wage growth.

In 2026 and 2027, the pace of macroeconomic expansion stabilises somewhat.

Exports generate moderate growth impulses. Business investment returns to an expansion path, bolstered by rising capacity utilisation and more favourable financing conditions. The latter, coupled with increasing real disposable income, also benefits private housing investment, which then embarks on a subdued recovery path too. Households

⁹ See the supplementary information entitled Underlying conditions for the Forecast for Germany.

see their purchasing power increase markedly again and increase their consumption somewhat more strongly. Taken together, government investment and consumption expenditure have a supportive effect throughout the forecast period.

Average annual GDP growth rate ⁴	- 0.2	0.1	1.1	1.0

Source: Federal Statistical Office (up to Q3 2024). Annual figures for 2024 to 2027 are Bundesbank forecasts. 1 Seasonally and calendar-adjusted index level in the fourth quarter of the previous year in relation to the calendar-adjusted quarterly average of the previous year. 2 Annual rate of change in the fourth quarter, seasonally and calendar adjusted. 3 As a percentage of GDP. 4 Discrepancies in the totals are due to rounding.

Under these conditions, the German economy grows only marginally next year, but somewhat more significantly in 2026 and 2027. Calendar-adjusted real GDP falls again slightly this year, by 0.2%, then grows by 0.2% in 2025, by 0.8% in 2026 and by 0.9% in 2027. The growth outlook is thus revised significantly downwards over the entire forecast period compared with the June Forecast – for 2025 most of all. This is primarily due to the more persistent weakness in the industrial sector, which is not only accompanied by a more persistent weakness in cyclical demand but is to a large extent considered to be structural now, too. The outlook for exports and industrial investment is thus considerably gloomier. The forecast for the increase in private consumption has also been revised sharply downwards. This reflects the significantly weaker labour market outlook, first and foremost.

Table 1.3a Revisions since the June 2024 forecast

Year-on-year percentage change

June 2024 forecast	0.0	0.3	1.1	1.4
Difference (in percentage points)	- 0.1	- 0.5	- 0.9	- 0.6

As the outlook is weaker, also due to structural factors, the expected potential output growth of the German economy has been revised considerably downwards.

Structural burden factors play a significant role in the subdued growth outlook, resulting in persistently weak estimates for potential output growth throughout the forecast horizon. The estimated potential rates between 2024 and 2027 stand at a mere 0.4% per year. ¹⁰⁾ The contributions to growth made by capital and total factor productivity(TFP) are lower than in the June projection, meaning that the recovery expected at that point in time will not materialise. ¹¹⁾ Beyond the forecast horizon, too, growth opportunities for the German economy appear very subdued from today's perspective, and as long as supply-side measures remain unforeseeable in concrete terms, a revival of potential growth seems unlikely.

The level of potential output in recent years is now also estimated to be significantly lower. In particular, the weak industrial activity that was already clearly discernible before the pandemic, and the slowdown in productivity growth following the financial crisis of 2008-09, are indicative of major structural burdens stemming from factors that have been at play for some time. These include demographic change, the tendency towards declining efficiency gains from the digital transformation, ¹²⁾ increasing protectionism, and also the trend slowdown in global trade that has been observed since the financial and economic crisis. ¹³⁾ From today's perspective, these dampening structural forces are deemed to be stronger, and consequently, there was a distinct downward

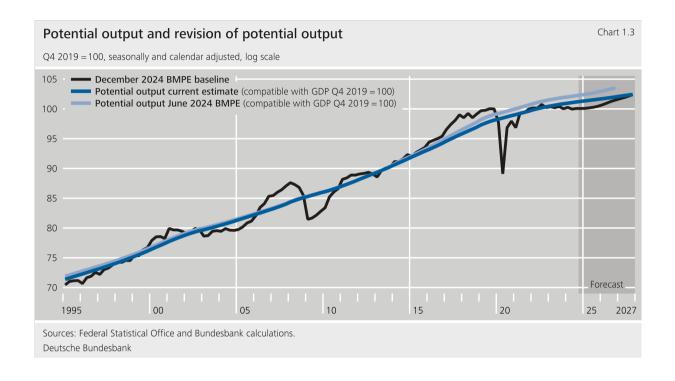

¹⁰ By comparison, it is estimated that potential growth averaged 1.4% per year in the period from 2011 to 2019.

¹¹ The rates for 2025 and 2026 were revised downwards by 0.1 and 0.2 percentage point respectively.

¹² See Deutsche Bundesbank (2023a).

¹³ See Deutsche Bundesbank (2023b).

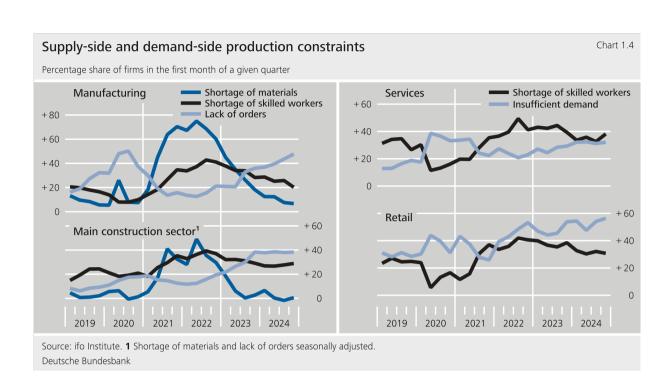

revision to growth in potential output retroactively for the years 2014 to 2019. ¹⁴⁾ At the same time, this means that the favourable development of economic activity in the years prior to the pandemic is classified as more cyclically induced.

The negative output gap will largely be closed by 2027. As a result of the revised estimate of potential output, the estimated output gap is smaller at the current end, thus also reducing the potential for catching up over the forecast period. However, the output gap is still negative at present. Now, the fact that aggregate demand is too weak is also likely to be a key factor in this again. ¹⁵⁾ This is indicated by the ifo Institute's survey data on production constraints, which largely show a shortage of orders or demand to be the biggest constraint on production. Given the expected recovery in economic activity, the output gap is largely closed by the end of the projection horizon in 2027.

¹⁴ This is reflected in lower than previously estimated contributions from trend TFP and capital input. By contrast, the estimate of potential growth in the period from 2020 to 2024 was already conservative and was revised only marginally in this Forecast.

¹⁵ Over the past few years, though, temporary supply constraints also played a role; see, for example, the box in Deutsche Bundesbank (2023c), pp. 15 f.

Supplementary information

Underlying conditions for the Forecast for Germany

The Forecast for Germany is based on joint assumptions by Eurosystem experts about the global economy, exchange rates, commodity prices and interest rates. These assumptions are based on information that was available on 20 November 2024. The forecast incorporates fiscal policy measures as soon as they are sufficiently specified and their implementation is considered likely.

External environment

The global economy will grow moderately over the forecast horizon. ¹⁾ Developments in global economic activity in the past summer half-year were largely in line with the assumptions made in the June Forecast for Germany. Domestic demand in the United States was somewhat more dynamic than expected. Alongside economic policy stimuli in China and the United Kingdom, this momentum boosts the global economic growth expected for next year. At the same time, the global outlook is dampened by a slower than expected growth in central and eastern European countries in June. After growing 3.4% this year, the global economy is expected to grow by 3.5% next year. In 2026 and 2027, it weakens again slightly to rates of 3.3% and 3.2%. For the United States, the incoming US administration's proposed extension to the tax cuts for households and enterprises under the "Tax Cuts and Jobs Act", set to expire at the end of 2025, will be taken into account. Other measures that are on the table, such as trade or immigration policy, have not been taken into account due to uncertainty regarding their implementation and design. ²⁾

¹ All data on global economic growth and global trade refer to global aggregates excluding the euro area.

² Some of them pose a significant risk to global economic developments, especially world trade. See also the supplementary information on the possible impact on the German economy of measures announced by the incoming US administration.

The economic recovery process in the other euro area countries continues.

Economic development figures in the other euro area countries on which the forecast is based are derived from the forecasts of the national central banks, which were incorporated into the projection for the euro area published by the ECB on 12 December 2024.

3) For the euro area excluding Germany, economic growth is therefore expected to increase from a rate of 1.1 % this year to 1.5 % and 1.7 % in 2025 and 2026, respectively. This means that the dynamics will only be slightly lower next year than in the June Forecast and will otherwise remain broadly unchanged. The growth rate is expected to decline slightly to 1.5 % in 2027.

While global trade is losing momentum, German sales market growth is regaining lost ground – in 2026 and 2027, both expand in line with global economic growth.

International trade increased more strongly in the 2024 summer half-year than expected in the June Forecast. Imports by the United States, the United Kingdom and some emerging market economies, in particular, grew sharply. The momentum in global trade is expected to weaken over the forecast horizon. Following an increase of 4.0% on average for the current year and of 3.6% next year, growth rates of 3.3% and 3.2% are expected for 2026 and 2027, which would be on a par with global economic growth. German exporters' sales markets are developing more slowly than global trade this year owing to falling imports by Germany's euro area trading partners. Next year, the dynamics of sales markets will then largely move closer to those of global trade. For 2026 and 2027, growth is expected to be in line with global trade dynamics.

In euro. 9 Calendar adjusted.

Commodity prices

Prices for energy commodities tend to decline over the forecast horizon. Concerns about demand have caused crude oil prices to decline since the summer, outweighing price-supporting factors such as the ongoing OPEC cuts and tensions in the Middle East. Forward quotations indicate a further decline in prices over the next three years. They are also below those given in the June Forecast. By contrast, natural gas prices in

the European wholesale sector have risen significantly since the summer. Their forward quotations have also picked up and are above the June assumptions. Developments in connection with the war between Russia and Ukraine may have played a role in this. In addition, European gas storage levels began to decline somewhat earlier than in previous years in view of an early cold spell. Higher demand for filling gas storage facilities is therefore expected in the coming summer season. Forward quotations suggest that European gas prices will nevertheless decline again after the winter of 2024-25. European electricity prices are also expected to decline on an annual average from 2025 onwards, with seasonal price increases in the forward quotations throughout the year anticipated during the winter months of each year.

Other commodity prices continue to rise initially, but decline somewhat after next year, with the exception of agricultural producer prices. Following a decline in the summer, other commodity prices have increased again somewhat in recent months. The rise in food commodity prices is also likely to have been abetted by crop failures caused by record-high global temperatures in the summers of 2023 and 2024. ⁴⁾ For total non-energy commodity prices, forward quotations indicate a further rise next year before decreasing slightly in 2026 and 2027. Euro area agricultural producer prices

⁴ SeeDeutsche Bundesbank (2024g).

continue to fall slightly on average this year. Growth is expected over the next three years, however, meaning that their level will be increasingly above that of the June Forecast.

Interest rates and exchange rates

Interest rate assumptions initially decline slightly before rising somewhat again.

The Governing Council of the ECB lowered key interest rates by 25 basis points at its monetary policy meetings in June, September and October 2024. On the cut-off date, EURIBOR forward prices were tilted to the downside up to 2026 before pointing slightly upwards again for 2027. They are thus below those of the June Forecast for the next two years. For ten-year federal bonds (Bunds), forward prices for the coming year show a broadly constant yield, which then rise slightly above the June Forecast assumptions from 2026 onwards. Financing costs for bank loans are also expected to decline slightly at first but then rise somewhat again, although they are likely to be lower than in the June Forecast.

The euro has depreciated since June 2024. Expectations regarding US monetary policy and the outcome of the presidential elections in the United States weighed on the euro. In the period that is relevant to the derivation of the exchange rate assumptions, it traded at US\$1.06, 1.9% lower than the assumptions made in the June Forecast. At 0.6%, the euro's depreciation in relation to 41 currencies important for German foreign trade was lower due to gains against some central European currencies.

Fiscal policy

There is no federal budget for 2025, and the forecast assumes that the rules for interim management of the budget will apply for the time being. Central government spending thus flows steadily even without new budget plans; a more restrictive policy is not necessary. ⁵⁾ The only planned but not yet adopted legislative change that has been taken into account is compensation for bracket creep in income tax. This is well-established and therefore assumed in all forecast years (as in previous Bundesbank Forecasts for Germany).

⁵ See Deutsche Bundesbank (2024b).

Temporary crisis measures will weigh on the government budget for the last time in 2024. Seen in isolation, the lapsing of these measures means that the deficit ratio will fall by just over 1 percentage point this year and by ½ percentage point next year. This year, the sizeable spending on energy price brakes in particular will come to an end. The revenue shortfalls resulting from inflation compensation bonuses, which are exempt from taxes, will occur for the last time in 2024. In addition, the reduced VAT rate on gas and heat was still in effect in the first quarter of 2024.

The overall contribution rate to the statutory social security schemes is assumed to rise to a record level over the forecast horizon. This is mainly due to the contribution rates to the statutory health insurance and long-term care insurance schemes. For 2025, the Federal Government is raising the supplementary contribution rates for health insurance institutions sharply and the contribution rate of the long-term care insurance scheme markedly. According to this forecast, the contribution rates to the statutory health insurance and long-term care insurance schemes will continue to increase significantly in subsequent years as well. The contribution rate for the statutory pension insurance scheme is assumed to rise somewhat in 2027. Rising contribution rates close funding gaps, which are mainly caused by sharply rising expenditure on benefits. ⁶⁾

The forecast assumes that bracket creep will continue to be offset retrospectively by corresponding adjustments to the tax rate. Revenue shortfalls also arise because income tax allowances for 2024 are raised again retroactively. In addition, the electricity tax for enterprises in the manufacturing sector will be lowered up to the end of 2025. By contrast, revenue from profit-related taxes will increase more strongly, especially from 2025 onwards, as a result of measures taken. The extended tax depreciation options in recent years have been used to accelerate depreciation, which is why depreciation is now correspondingly lower– and tax revenue thus higher.

In further measures, additional revenue and expenditure are partly intertwined.

Revenue from carbon emission allowances also rises gradually over the forecast horizon, financing expenditure by the Climate Fund. The extended HGV toll generates additional revenue this year, much of which flows into the modernisation of the rail network. By contrast, lower revenue will occur in 2027 because the EU's Next Genera-

⁶ See Deutsche Bundesbank(2024b).

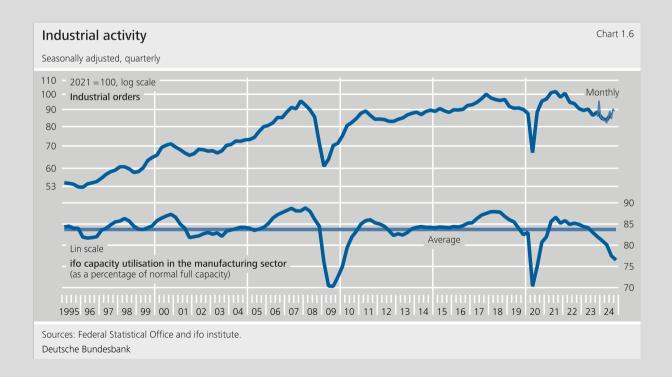

tion EU programme comes to an end. Given the central government's tighter financial situation, the forecast now assumes that it will then phase out some of the associated expenditure.

Supplementary information

Details on the forecast of expenditure components

Exports only return to a moderate expansion path over the course of next year.

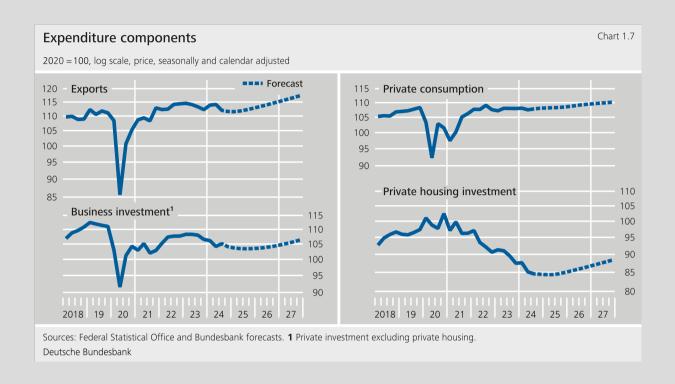

Despite robust growth in sales markets, exports are again unlikely to provide any stimulus to macroeconomic growth in the current winter half-year. Industrial orders received from abroad improved somewhat in the third quarter but remain at a low level. Correspondingly, according to the ifo Institute, German exporters are predominantly pessimistic about the near future. The situation is likely to improve slowly only later next year. Against the backdrop of a robust global economy and firming and continuously growing demand from abroad, the export industry should slowly regain traction. However, the competitive environment remains challenging and the pressure to adapt is high. Correspondingly, exports expand at a substantially weaker pace than the sales markets over the entire forecast horizon. German exporters thus continue to concede market share and exports contribute less to economic growth than in previous recovery periods.

With a significant delay, business investment is likewise beginning to recover. The investment environment for German enterprises is currently extremely challenging. The protracted weakness of the export industry and the subdued domestic demand for capital goods, which was also due to the previous monetary policy tightening, led to significant underutilisation of capacity in the manufacturing sector. In addition to the economic headwinds, structural impediments are also weighing on the propensity to invest. Against this backdrop, the sentiment of capital goods producers is still markedly subdued, according to the ifo Institute, and lending to non-financial corporations likewise remains at a low level. Industrial investment is therefore likely to decline further into the year ahead. Only after the economy has expanded for several quarters, capacity utilisation has improved again and the dampening effects of monetary policy tightening have subsided does business investment return to a path of recovery. As a result, business investment only makes another slight contribution to GDP expansion in 2026 and a somewhat stronger one in 2027.

Private consumption grows only slightly at first, but somewhat more strongly from **2026 onwards.** Following the erosion in purchasing power caused by high inflation, labour income rises more strongly than consumer prices for some time now. However, this has not yet had a particularly stimulating effect on private consumption, as other headwinds have persisted. Uncertainty - stemming from the ongoing period of economic weakness, the political environment and geopolitical conflicts – is high. In addition, the labour market has recently deteriorated markedly and concerns about job security are likely to have risen. Against this backdrop, private consumption fell well short of the expectations in the June Forecast. It contracted markedly in the second quarter, and increased only slightly in the third quarter despite sharply rising wages, leading to a significant increase in the saving ratio. It is also likely to rise at least slightly in the current quarter. This is indicated by the available indicators, such as the sharp increase in private vehicle registrations in October. According to the GfK survey, the propensity to purchase was also higher than in the previous quarter on average in October and November 2024. However, the overall GfK consumer climate index deteriorated again. Private consumption will grow only slightly next year, as real disposable income will actually decline slightly following its previous sharp rise. This will be caused not only by the weaker labour market, but also the fact that households, faced with the end of tax-free and social contribution-free inflation compensation bonuses and significantly increased social security contributions, will take home even less of their gross pay – which will itself have increased to a lesser extent – than in the current year. However, they are likely to smooth their consumption slightly by lowering their increased saving rate. Real disposable income rises markedly again in 2026 and 2027, mainly due to declining inflation and wages rising somewhat more sharply again. As

the economy brightens and the labour market improves again, precautionary motives also subside and the saving ratio declines somewhat further. Private consumption therefore picks up some momentum again.

Housing investment tentatively rebounds from mid-2025. Housing investment has declined significantly in recent years, its level now equalling a low it last reached in 2013. 1) The decline has continued and was even stronger than in the June Forecast. However, there are signs that – similar to expectations – the housing market is stabilising and housing investment is slowly approaching its trough. For example, housing prices have recently started to rise again for the first time since 2022. Although construction permits had declined until recently, new orders in housing construction rose for the second time in a row in the third quarter. This stabilisation of demand is likely to be helped by a significant slowdown in the growth of construction costs and by the fact that the effective interest rates on housing loans have already fallen a little in the wake of monetary policy easing. Nevertheless, the general level of demand is still weak. According to ifo surveys, more than 50 % of firms in housing construction are still complaining about order shortages. Housing investment is therefore likely to decline slightly in the current quarter and first quarter of 2025 before starting a slow recovery.

¹ This picture is more drastic than in the June Forecast, as current housing investment was revised noticeably downwards in August.

There is a general demand for additional housing. ²⁾ The comparatively favourable price-to-rent ratio is also likely to have a supportive effect. ³⁾ The recovery then picks up a little more momentum in the following two years, driven in particular by more favourable financing costs and improving household incomes. The high demand for energy-efficient renovations of existing properties is another supporting factor. Overall, however, the housing supply will only be expanded to a limited extent. This leads to some upward pressure on house prices. They therefore continue to grow, albeit at significantly lower rates than in the low interest rate period.

Sources: Federal Statistical Office and Bundesbank calculations. **1** Effective annual interest rate plus costs. Volume-weighted average interest rates for all new agreements concluded for deposits and loans during the reporting month.

Deutsche Bundesbank

Real government demand rises significantly over the forecast horizon. Government investment increases sharply up until 2026 and then falls somewhat in 2027. On the one hand, military spending rises sharply up until 2026. On the other hand, construction investment does not fully maintain its current level, as the fiscal positions of central, state and local government are tighter. Government consumption rises fairly continuously, mainly due to higher spending on health and long-term care.

² This is especially true in major conurbations. In addition to high levels of immigration, this is also due to the rising number of one-person households, which causes an increase in living space used per person.

³ Real estate prices fell sharply from mid-2022, while rents increased markedly. The price-to-rent ratio is therefore significantly more favourable than in the years before 2022. In the forecast period, real estate prices rise again somewhat more strongly than rents, but their ratio remains comparatively favourable.

Real imports grow noticeably again from next year, with the current account surplus falling slightly below 6 % of nominal GDP. The ongoing economic weakness is also reflected in real imports, which are expected to decline again slightly this year. They then go back up again, if moderately, in 2025, followed by more significant increases in 2026 and 2027 as the economic recovery solidifies. As domestic demand is more buoyant than exports, imports exceed the growth in exports over the entire forecast period, especially next year. As terms of trade improve only slightly at the same time, the trade balance (as a share of nominal GDP) declines significantly in 2025 before moving more or less sideways over the remainder of the forecast horizon. This contributes to the fact that the current account surplus, which is expected to fall slightly above 6 % of GDP this year, falls slightly below 6 % of GDP next year and remains at this level in subsequent years.

1.2 Temporary marked weakening of labour market

The labour market was impacted noticeably by the ongoing weakness of the German economy – but it remains fairly robust. June expectations of an imminent recovery in the labour market did not come to fruition. Employment growth, which had previously already been muted, turned negative in recent months and unemployment went up more strongly than expected. After many years of very favourable labour market figures, this deterioration appears particularly striking. ¹⁶⁾ However, this should not detract from the fact that the labour market essentially remains fairly robust, including compared with previous episodes of weak growth. The level of employment is high and unemployment is relatively low, and with firms caught between persistently weak demand and a demographically-induced structural shortage of skilled workers, they are avoiding major layoffs as far as possible. While firms significantly reduced their use of temporary agency employment, they have so far largely retained their core workforces, thereby also accepting lower labour productivity. ¹⁷⁾ In addition, empty working time accounts and low overtime are pushing down average working hours. 18) For demographic reasons, many employees are currently entering retirement. This offers opportunities to shrink headcounts without compulsory redundancies, by not fully replacing staff. The number of vacancies decreased significantly in this context, but is still quite high by historical standards. This is partly because, in the context of structural change, some sectors are benefiting from increased labour demand. 19)

Given that the German economy remains stagnant, employment is likely to decline in the current winter half-year as well. The longer business activity remains weak, the more likely it is that there will be increased layoffs in the manufacturing sector, in particular, but also in the trade sector, which is suffering from subdued consumption. This is indicated by the ifo Institute's Employment Barometer, which is deep in negative terri-

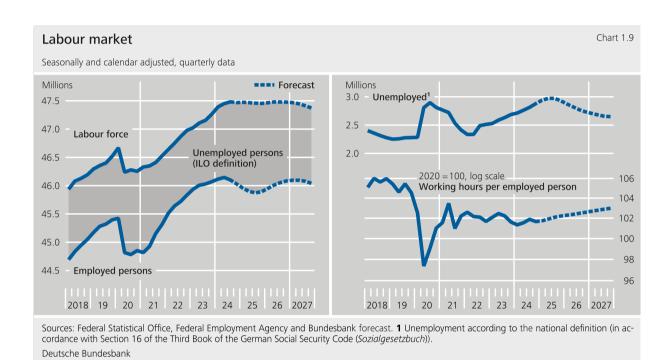

¹⁶ Additionally, the data only began to look like this after a certain delay. In particular, the months from June 2024 onwards were revised downwards when the Federal Statistical Office published the employment figures on 30 October 2024. Besides the lower level of employment, this chiefly painted employment growth more negatively than before. See Deutsche Bundesbank (2024b), Chapter 3 "Labour market cooled in the third quarter".

¹⁷ Only the manufacturing sector is making slightly greater use of short-time working arrangements. This instrument serves to bridge short-term demand shortfalls and is less suitable for many firms in the current situation.

¹⁸ The decline due to the persistent trend towards part-time work and a still high level of sick leave is also playing a role.

¹⁹ In particular, this refers to demand for healthcare and nursing staff, childcare staff, engineers and IT specialists, as well as skilled staff for qualified business services.

tory here. However, seeing as the sectors benefiting from structural change are likely to continue hiring, the decline in employment should remain limited overall. Other leading indicators, such as the IAB labour market barometer, also suggest that the labour market is still fairly resilient overall. Nevertheless, unemployment is likely to see a further moderate increase. ²⁰⁾ Part of the reason for this is that there is less of a match between existing and in-demand jobs and qualifications due to shifts in the economic structure.

The economic recovery gradually taking hold in the course of 2025 is initially unlikely to lead to increased hiring in the labour market. Employment is expected to go down again slightly in 2025. In conjunction with the decline in employment that has been ongoing since mid-2024, there is thus a marked decrease in the average number of persons in employment over 2025. However, existing staff should be put to greater use again over the course of the year, clawing back some of the depressed level of productivity and working hours. Against this backdrop, unemployment continues to rise well into next year. The labour market outlook for 2025 is thus distinctly weaker than in the June Forecast.

²⁰ Data that became available after the Forecast was finalised were somewhat better than expected. However, they confirmed the underlying trends in the Forecast, showing a further (albeit only marginal) uptick in unemployment in November and slightly (and primarily in the manufacturing sector) declining employment in October.

Over the remainder of the forecast period, the labour market recovers again, but remains less tight than expected in previous forecasts. From 2026 onwards, the economic recovery leads to rising employment, falling unemployment and an increasing shortage of skilled workers. Working hours and labour productivity also recover further. The labour market is thereby faced with the challenging situation in which the labour supply shrinks from 2026 for reasons of demographics, even though individual labour force participation continues to rise and the assumed level of immigration is significant. ²¹⁾ The pace at which refugees are being integrated into the labour market had recently improved markedly. ²²⁾ However, it takes time and effort to integrate both immigrants and the unemployed, of whom greater job and geographical mobility is required due to structural change. Unemployment therefore declines only moderately and, in 2027, will not yet have returned to its lowest levels from before the outbreak of the COVID-19 pandemic.

1.3 Much weaker wage growth in future after another strong year in 2024

As of next year, negotiated wages lose significant momentum in view of lower inflation rates, prolonged economic weakness and the deterioration in the labour market. Since the Forecast for Germany in June, negotiated wage agreements up to October have largely been higher than expected. However, employees have also ended

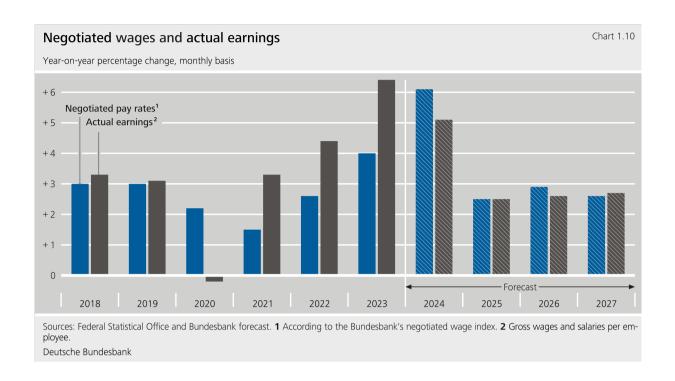

²¹ In the year to date, immigration has been somewhat lower than expected in the June Forecast. According to the Federal Statistical Office's migration statistics, a net figure of 272,000 people moved to Germany up to August, around one-third less than in the same period of the previous year. For 2024 as a whole, a net figure of 480,000 persons is expected, which will decline further in the subsequent years (2025: 400,000 persons, from 2026: 300,000 persons per year).

²² See Deutsche Bundesbank (2024b), Chapter 3 "Labour market cooled in the third quarter".

up having to adjust their wage expectations in part to the changed economic environment. The metals and electrical engineering sector, for example, recently agreed on wage increases that are distinctly lower than the expectations expressed in the June Forecast; this was due to persistently weak economic activity and the pressure to adjust that the sector is facing. ²³⁾ Lower inflation rates, sluggish economic activity and weakened labour demand also suggest that, in general, more moderate agreements will be reached in the coming months than in previous years. Highly heterogeneous levels of activity in different sectors are thus likely to come to the fore. ²⁴⁾ Next year, the elimination of the inflation compensation bonuses also dampens wage growth, as these are only partly replaced by regular wage increases. Wage growth sees a sharp drop to 2.5 % on an annual average. In 2026, negotiated wages grow somewhat more strongly again. This is still under the influence of large agreements running for long terms that were reached during the period of high inflation, however; these are no longer relevant in 2027. The broadly normalised level of activity and the once again tighter labour market then lead to historically slightly above average growth in negotiated wages of 2.6 %. Compared with the June Forecast, the latest agreements, in particular, bring about a small upward revision in this year's forecast of negotiated wages. The weaker outlook for economic activity and the labour market only becomes more evident in subsequent years; the increase in negotiated wages for 2025 and 2026 has therefore been revised downwards noticeably.

²³ Survey results likewise point to major burdens in such a scenario. According to a special survey among manufacturing firms conducted before the US election by ifo Institute, 44 % of German industrial firms expected negative impact on their business as a result of Donald Trump's election; 5 % expected a positive impact, and 51 % expected it to make no difference who won the election; see CESifo (2024).

²⁴ Ongoing labour market shortages are evident in some of the better-performing services sectors. The negotiating parties in those sectors will therefore probably tend to agree on higher wage increases. See Deutsche Bundesbank (2024d). All past pay agreements included in the Bundesbank's negotiated wage statistics (around 550 collective wage agreements and provisions governing civil servant pay) are factored into the forecasts of negotiated wage increases. They are extrapolated beyond their contractual terms, taking into account the overall economic situation and industry-specific factors.

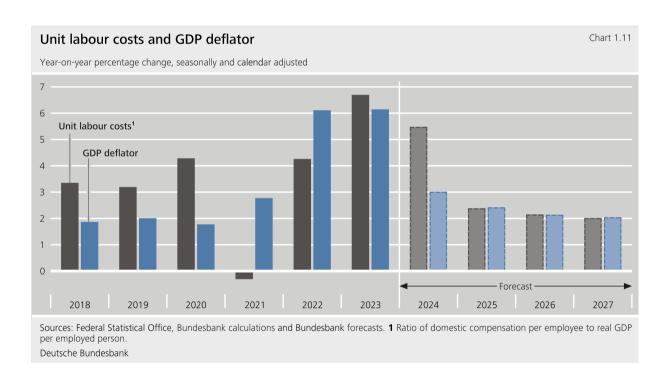

Actual earnings growth is initially weaker than that of negotiated wages. In the current year, growth in actual earnings is once again very high by historical standards, but it is already below that of negotiated wages. This is because actual earnings respond more quickly to the significant changes in macroeconomic conditions. On account of sluggish economic activity and the weakening labour market, for example, industrial groups reduce their profit-sharing and the number of paid overtime hours is reduced to a small amount. Only in 2027, when economic activity picks up and labour market tightness increases, do actual earnings again show slightly stronger growth than negotiated earnings. Labour costs, measured as compensation per employee, rise somewhat more strongly than actual earnings, especially in the coming year. This is due to an additional cost surge for employers in the form of higher social contribution rates.²⁵⁾

Domestic inflation as measured by the GDP deflator declines to 2% by 2027 on the back of profit margins normalising and an easing of pressure from unit labour costs. As in the previous year, economic output is slightly lower this year with employment

²⁵ See the supplementary information on the underlying conditions for this Forecast. See also Chapter 2 "Outlook for public finances".

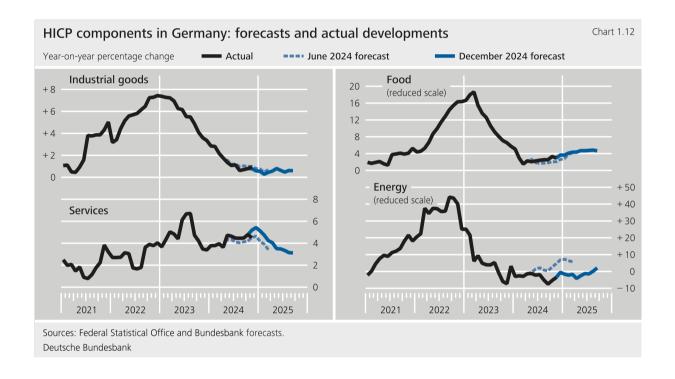

still robust overall and wages rising strongly. As a result, domestic price pressures from unit labour costs remain very high. However, firms have been cushioning this pressure through lower profits for about a year now. In previous years, they were still able to expand their profit margins strongly, but the underlying conditions for this have largely changed. Aggregate demand, in particular, is now significantly weaker. Tighter monetary policy is likely to have been one factor here. Against this backdrop, aggregate profit margins fall strongly this year, roughly returning to their pre-pandemic levels. As measured by the GDP deflator, the previously significant domestic inflation will therefore fall significantly to 3.0 %, despite the substantial rise in unit labour costs. In the remainder of the forecast period, profit margins decline only marginally before stabilising in 2027, meaning that their contribution to further disinflation is only small. However, the rise in unit labour costs declines markedly from next year, as wage growth recedes and labour productivity slowly recovers. Against this backdrop, domestic inflation continues to decline markedly, to 2.0 % in 2027.

1.4 The inflation rate is still elevated in 2025, but then gradually returns to 2%.

The inflation rate was lower than expected recently. Consumer price inflation, as measured by the HICP, stood at 2.4 % in November, 0.8 percentage point below the

rate expected in the June Forecast for Germany, primarily because energy prices fell more sharply than expected. Food prices rose much more strongly than anticipated, however. The rate excluding energy and food (core rate) was roughly in line with expectations. Price increases for services tended to be stronger than expected, whilst inflation for non-energy industrial goods declined somewhat faster than projected. At 2.5 % in the current year overall, the inflation rate is expected to be slightly lower than expected in June.

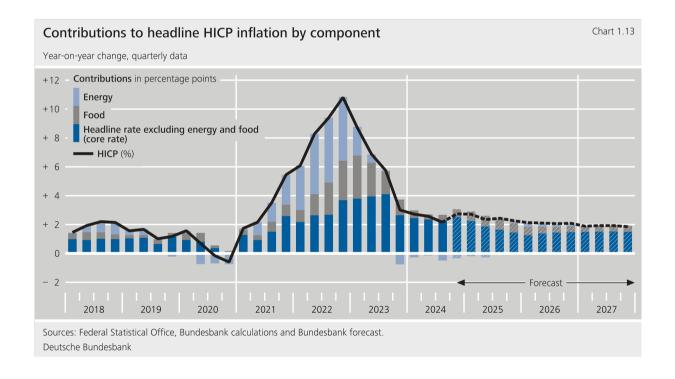

Inflation remains elevated next year, mainly due to service price increases abating only slowly. The weak economy is generally having a price dampening effect on services, too. However, the previously sharp rise in wages is still exerting upward pressure on consumer prices with a certain time lag. ²⁶⁾ Particularly strong price increases as of the beginning of 2025 were announced for public transport and insurance services. ²⁷⁾ The rise in rents, too, is initially expected to be higher than average by historical standards, as existing rents are only slowly adjusting to the cost surges of

²⁶ See Deutsche Bundesbank (2019a).

²⁷ The price for the "Deutschland-Ticket" is set to go up from €49 to €58 in January 2025. Furthermore, the Association of Private Health Insurance Funds (*Verband der privaten Krankenversicherungen – PKV*) predicts exceptionally strong increases in contributions at the turn of the year. Taken together, alone the announcement of these two price increases, adjusted for the price increase generally expected in these areas, is likely to lead to a rise of +¼ percentage point in the core rate in all months of 2025 (headline inflation: around +0.2 percentage point).

recent years. In addition, forward-looking booking data suggest further strong price increases for package holidays in the coming months. ²⁸⁾ By contrast, inflation for nonenergy industrial goods has already fallen markedly and is likely to decline further somewhat, partly in view of weak demand. The core rate overall is expected to decline from 3.3 % in 2024 to 2.4 % in 2025. By contrast, food prices will rise more strongly again next year. This is because agricultural producer prices are markedly higher, especially for milk fats. In addition, the recent very high wage growth in the retail sector is likely to still have an impact. Lastly, in 2025, energy prices no longer dampen the headline inflation rate as strongly as during this year. Energy commodity futures prices are on a slight downturn but this is partly offset by a further increase in the carbon price and a substantial rise in network charges for gas transmission. ²⁹⁾ Headline HICP inflation therefore drops only marginally to 2.4 % in 2025.

In the remainder of the forecast period, the inflation rate in Germany gradually returns to 2%. Monetary policy tightening still has an impact and the pressure exerted by unit labour costs continues to ease. The core rate therefore initially drops to 1.9% in 2026. With the recovery in economic activity and the return to an almost normal level of

²⁸ In the package holidays subcomponent of the HICP, prices are recorded according to their travel date, not the booking date; seeSchnorrenberger, Schwind andWieland(2024).

²⁹ SeeDeutsche Bundesbank (2019b).

aggregate capacity utilisation, it rises slightly to 2.0 % in 2027. Food inflation declines somewhat again in 2026 and 2027, but still remains elevated. This is because prices for agricultural commodities and labour costs continue to generate above-average price impulses, albeit with a declining tendency. Energy prices go back up noticeably in 2026, especially as the national carbon price continues to rise, while the fall in market prices for energy is assumed to be significantly less strong than in the previous year. Energy components are then expected to have a slight dampening effect again in 2027. This is mainly due to the assumption that the national carbon price will be transferred to the European ETS2 and that a slightly lower carbon price will therefore be set. ³⁰⁾ Headline inflation falls to 2.1 % in 2026 and 1.9 % in 2027. This means that over the entire forecast horizon the outlook for inflation improved slightly compared to the June Forecast.

Table 1.3b: Revisions since the June 2024 forecast

Year-on-year percentage change

Item	2023	2024	2025	2026
Harmonised Index of Consumer Prices				
December 2024 forecast	6.0	2.5	2.4	2.1
June 2024 forecast	6.0	2.8	2.7	2.2
Difference (in percentage points)	0.0	- 0.3	- 0.3	- 0.1

³⁰ It is assumed that the price will thus fall from €65 to €59 per tonne of CO₂ For 2027, this corresponds to the price ceiling of €45 for 2020 prices as set out in the EU ETS2 system.

2 Outlook for public finances

There is only a slight fall in the deficit ratio from 2.6 % in 2023 to 2.5 % in 2024, even though the extensive burdens caused by the energy price brakes have dropped (see the supplementary information entitled <u>Underlying conditions for the Forecast for Germany</u>). This is because spending on the Armed Forces Fund and the Climate Fund, staff and interest, as well as on pensions, healthcare and long-term care, is rising sharply. In addition, tax refunds stemming from a court ruling on capital gains tax are placing a one-off burden. ³¹⁾ At the same time, revenue is still showing quite dynamic growth, especially as wages are rising strongly and contribution rates to the social security funds are going up.

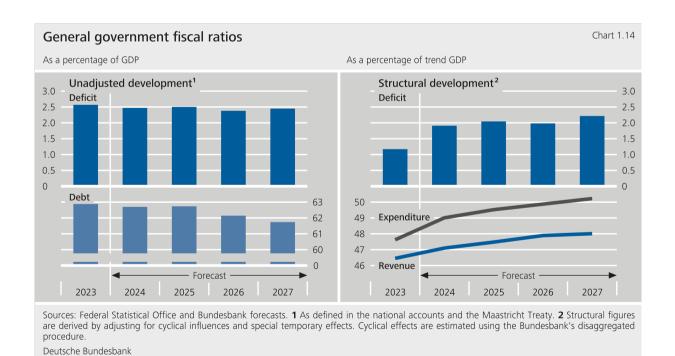

In 2025, the deficit ratio remains unchanged at 2.5 %, although the revenue and expenditure ratios continue to rise significantly. Significant budgetary relief compensates for corresponding burdens elsewhere. On the one hand, significant additional revenue is generated by the fact that fees subject to compulsory contributions are taking the place of tax- and social contribution-exempt inflation compensation bonuses in some cases. In addition, the court ruling on capital gains taxes is no longer applicable, and transfers to Ukraine are less of a burden. On the other hand, the weak economy is becoming more noticeable as the nominal reference variables of taxes and social contributions rise more slowly. Furthermore, in some areas expenditure is still growing at dynamics similar to 2024. The deficit in the social security funds shows little change on balance: health and long-term care insurance schemes are increasing contribution rates once again, thus reducing their deficits overall. By contrast, the unemployment insurance scheme and, above all, the pension insurance scheme are expanding their deficits. Reserves are used to prevent contribution rates from rising here as well in order to offset the deficit.

The deficit ratios for 2026 and 2027 are both 2.4%, with only a small change in the revenue and expenditure ratios. The Forecast assumes that central, state and local

³¹ In March of this year, the Federal Fiscal Court ruled that foreign investment funds that invested in German enterprises had been unlawfully subject to capital gains tax in the past. The national accounts record the sum of expected repayments, at just under ¼% of GDP in 2024, as capital transfers.

government spending will lose momentum due to budgetary strains, especially in the areas of personnel, intermediate consumption and investment. Growth in expenditure on pensions, healthcare and long-term care will continue to outpace that of the reference variable for social security contributions. The health and long-term care insurance schemes continue to avoid incurring deficits through renewed increases in contribution rates. However, there is significant growth in the pension insurance scheme's deficit.

The structural deficit ratio remains relatively stable at around 2% over the forecast horizon from 2024 to 2027. This ratio factors out temporary influences (primarily crisis measures and economic activity). Around three-quarters of the structural deficit is attributable to central government (including its off-budget entities). Using its own calculation method, central government initially computes significantly higher cyclical burdens on its budget and first uses up its disposable reserves. This makes it easier for central government to comply with the debt brake borrowing limit, as cyclical deficits and deficits financed from reserves are not counted towards the limit. In 2026 and 2027 in particular, the results forecast here indicate a marked overshooting of the borrowing limit, however. In addition, the Armed Forces Fund is estimated to record a deficit of ½% of GDP in each of these two years. At the end of 2027, the forecast expects it to still have a residual borrowing authorisation of ¼% of GDP.

There is a moderate decline in the Maastricht debt ratio from 62.9% at the end of 2023 to 61.7% at the end of 2027. Central, state and local government deficits lead to a

significant increase in debt. Nominal GDP growth in the denominator is not sufficient to stabilise the ratio. However, the government will be repaying debt related to the coronavirus and energy price assistance loans and bad bank portfolios from the financial crisis. The deficits in the social security funds do not increase government debt, as they are financed from reserves. From today's perspective, the share of EU debt (especially that incurred through NGEU) which Germany ultimately has to repay on a pro rata basis is just over 2 % of GDP in 2027. This is not included in the Maastricht debt ratio.

3 Risk assessment

The macroeconomic forecast presented here is subject to a number of uncertainties.

Risks currently exist, in particular, in relation to growing protectionism, geopolitical conflicts and the impact of structural change on the German economy. Following the Bundestag elections, fiscal and economic policy could also see significant change. All in all, risks to economic growth are currently tilted to the downside and risks to inflation to the upside.

Rising geopolitical tensions or increased protectionist measures entail significant downside risks to economic output and upside risks to inflation. Should Russia's war against Ukraine or the conflicts in the Middle East intensify or spread, this could constrict the supply of energy commodities in the global market and disrupt supply chains. Via rising import prices, this would directly increase inflation in Germany and constrain economic activity. Growing trade policy tensions would probably have similar effects. This threat will become fairly imminent if the incoming US administration implements its announced trade policy plans – especially in the event of huge tariff increases and possible retaliatory measures. In such a risk scenario, the German economy would probably suffer considerably; see the supplementary information below. ³²⁾

³² Survey results likewise point to major burdens in such a scenario. According to a special survey among manufacturing firms conducted before the US election by ifo Institute, 44 % of German industrial firms expected a negative impact on their business as a result of Donald Trump's election; 5 % expected a positive impact, and 51 % expected it to make no difference who won the election; see CESifo (2024).

Supplementary information

The possible impact on the German economy of measures announced by the incoming US administration

The re-election of Donald Trump as US President could well initiate a drastic pivot of the nation's trade and economic policy. The plans announced in the run-up to the US election are pointing in that direction. At present, however, they are not sufficiently specified, nor is it certain enough that they will be implemented, for them to be included in the baseline forecast. For the purpose of the risk assessment, we gauge the potential impact of a more restrictive trade policy and other measures put forward by the incoming US administration.

In particular, the drastic tariff increases on the table are likely to play an important role in this. Tariffs on US imports from China, for instance, could rise to 60 %. For products from Germany and other economies, the new tariff rate could be 10 %. ¹⁾ In some cases, designated members of the incoming US administration have raised the prospect of even more draconian measures. ²⁾ Retaliatory measures by trading partners would then be likely. As a highly export-oriented country whose exporters are relatively strongly exposed to the US market, Germany may be more affected than other economies by the consequences of a restrictive US trade policy.

The potential impact of a risk scenario on the German economy is quantified below. The scenario assumes US tariffs of 60 % on imports from China and 10 % on products from Germany and other economies, as well as tit-for-tat retaliation by trading partners.

¹ This corresponds to an increase of just under 49 percentage points in the effective average tariffs on Chinese products. Tariffs on products from other regions of the world would be raised by an average of just under 9 percentage points.

² For instance, general tariffs could also be raised, by up to 20 percentage points. An additional 25 % could be tacked onto tariffs on Mexican and Canadian products unless US demands for greater border security and the fight against drug trafficking are addressed.

³⁾ It also takes into account tax relief promised by President-elect Trump and the Republican Party during the election campaign. ⁴⁾ In addition, given statements to that effect from the incoming US administration, it considers the consequences of the mass deportation of immigrants living and working in the United States. ⁵⁾ Finally, it is assumed that the macroeconomically relevant uncertainty will increase in this environment. ⁶⁾ The risk scenario ignores the potential macroeconomic effects that other measures, such as new deregulation initiatives, could have in the United States.

The macroeconomic implications of US policy measures for Germany are estimated using the National Institute Global Econometric Model (NiGEM) and the Bundesbank's macroeconomic model (BbkM- DE). NiGEM comprehensively models global trade linkages and can also illustrate the implications of trade policy disruptions. ⁷⁾ It can do the same for impacts on Germany. However, the model does not explicitly focus on the German economy. For this reason, the BbkM- DE model deployed for the Bundesbank's macroeconomic forecasts is also used to obtain a view of the German economy specifically. The simulations using BbkM- DE are based on the effects relating to Germany's international environment identified by NiGEM. ⁸⁾ The effects on the German economy

- 3 It is assumed that, beginning in the first quarter of 2025, tariffs will be gradually raised up to the assumed levels within two years. For their part, trading partners are assumed to retaliate by imposing tariffs of the same size on imports from the United States. The assumption of tit-for-tat retaliation is based on the experience gained from the 2018 US-China trade war. It is expressly neither an interpretation of statements from major US trading partners' governments nor a policy recommendation. It is assumed that tariffs between the EU and China will remain unchanged.
- 4 Additional tax relief for households is assumed as from the fourth quarter of 2025. Income from overtime hours worked and social security benefits are assumed to be exempt from tax in future. In addition, the corporate tax rate is reduced from 21 % to 15 % in the scenario. The prospect has been raised of extending the tax cuts under the Tax Cuts and Jobs Act signed into law during the first Trump administration and set to expire at the end of 2025; this extension already forms part of the forecast baseline and is therefore not assessed in this risk scenario. For a quantification of the fiscal costs of these measures, see Committee for a Responsible Federal Budget (2024).
- 5 The scenario assumes that, from the third quarter of 2025 onwards, undocumented immigrants will be deported on a mass scale, reducing the labour force by 1.3 million by the end of 2027. The forecast baseline already assumes that the strong influx of immigration to the United States in recent years will come to a halt under President-elect Trump.
- 6 The analyses are based on changes in financial market uncertainty. This indicator is based on the volatility of the non-predictable component of a wide range of macroeconomic data and financial market variables. For a discussion of the conceptual advantages of examining financial market uncertainty over alternative approaches, see Deutsche Bundesbank (2020).
- 7 NiGEM is a semi-structural model designed by the National Institute of Economic and Social Research that models the economies of most OECD countries and major emerging market economies (see Hantzsche et al. (2018)). A current model extension expressly permits the simulation of trade policy measures. See Bernard et al. (2024).
- 8 Any feedback the macroeconomic effects in Germany from the calculations using BbkM- DE have on or via the global environment is thus not explicitly taken into account. In the simulations with BbkM- DE, it is implicitly regarded as part of the assumptions derived from NiGEM regarding the external environment (for details on BbkM- DE, see Haertel et al. (2022)). Both models have been used for a wide range of simulation and scenario analyses, including some as a combination of NiGEM (for the international environment) and BbkM- DE (for the German economy); see Deutsche Bundesbank (2022b, 2024e).

triggered by heightened uncertainty are estimated using a structural vector autoregression (SVAR) model. $^{9)}$

According to the NiGEM simulations, protectionist measures, in particular, noticeably dampen economic activity in the United States. In the simulations, losses in consumer purchasing power and increased costs for intermediate inputs outweigh US industry's price competitiveness in the domestic market. In addition, the retaliatory tariffs affect the profitability of US firms' foreign business. ¹⁰⁾ The reduced labour supply also weighs on US GDP. Although tax relief counteracts this, the negative impact of tariff increases, in particular, clearly predominates. Overall, the US economy suffers annual growth losses averaging around 0.7 percentage point from 2025 to 2027. The tariff-induced rise in import and consumer prices and second-round effects via higher wages drive up inflation in the United States sharply. Inflation already exceeds the baseline by 0.4 percentage point in 2025 and by more than 1.5 percentage points in 2026 and 2027. ¹¹⁾ Without a significant monetary policy tightening in the United States, the surge in inflation is even stronger and more persistent. In anticipation of interest rate hikes, the US dollar also sees a substantial and immediate appreciation.

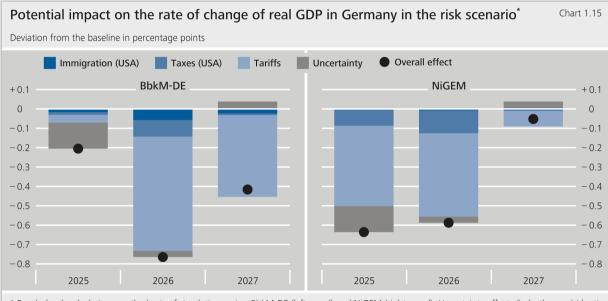

The German economy is also likely to suffer considerably, across models, from such a US policy shift. Its strong reliance on exports makes it particularly vulnerable to the decline in foreign demand resulting from the global trade losses triggered by the restrictive trade policy. The heightened uncertainty further burdens the German economy. The depreciation of the euro resulting from the simulations, which, in and of itself, strengthens price competitiveness, cannot compensate for this. As a result, according to the simulations with BbkM- DE and NiGEM, GDP growth is significantly lower than in the baseline forecast, with differences between the models regarding the timeline of growth losses (see Chart 1.15). According to NiGEM, the burdens would already become clearly noticeable in 2025 but last for a shorter duration. Overall,

⁹ The SVAR model comprises a stock price index, a measure of financial market uncertainty, a shadow interest rate as a measure of monetary policy orientation, the HICP, the unemployment rate and quarterly real GDP. To generate impulse responses, the recursively identified uncertainty shock is calibrated according to its movement during the first Trump administration. The SVAR results are added to the simulation results of NiGEM and BbkM- DE regarding GDP and inflation in Germany.

¹⁰ Simulation studies by Bernard et al. (2024), McKibbin et al. (2024) and Goldman Sachs (2024a) also clearly assess the macroeconomic effects of a more restrictive trade policy as negative from the perspective of the United States. Analyses by the International Monetary Fund (2024) also point to considerable downside risks to U economic growth in a similar scenario.

¹¹ Simulation calculations with other models produce, in some cases, significantly lower inflation effects; see, for example, Goldman Sachs (2024a). In other studies, including McKibbin et al. (2024), by contrast, they are even larger. The magnitude of the inflation effects largely depends on how wages respond to the rise in the cost of living caused by the additional tariffs.

economic output in Germany in 2027 would be 1.4% below the baseline according to BbkM- DE and 1.3% below the baseline according to NiGEM. The simulation results presented here thus point, across models, to considerable downside risks to economic growth in Germany. ¹²⁾

* Bundesbank calculations on the basis of simulations using BbkM-DE (left panel) and NiGEM (right panel). Uncertainty effects (in both cases) identified using a satellite model (SVAR).

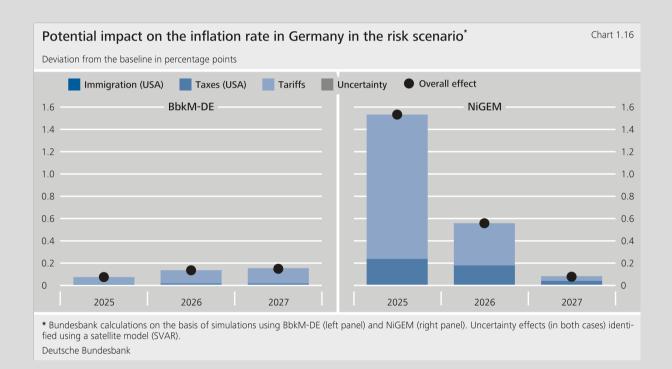

Deutsche Bundesbank

The inflation effects differ significantly more strongly in the simulation calculations.

According to BbkM- DE, the inflation effects in Germany would be small in the forecast period up to 2027, with annual inflation being 0.1 to 0.2 percentage point higher (Chart 1.16, left panel). In NiGEM, on the other hand, the inflation rate rises sharply by around 1.5 percentage points, especially in 2025, but in 2026, the inflation rate is still 0.6 percentage point higher (Chart 1.16, right panel). The main reason for the large differences is the rapid and extensive transmission of exchange rate effects and retaliatory tariffs to domestic consumer prices in NiGEM. This is also due to the assumption that all imports are invoiced in US dollars. This is why the depreciation of the euro against the

¹² Other studies show GDP effects in Germany of similar magnitude (see Dullien et al. (2024), Goldman Sachs (2024b), Obst et al. (2024), and Zandi et al. (2024)) or a smaller magnitude (see Felbermayr et al. (2024)). However, it should be noted that comparability may be limited because the specific design (e.g. the size and timing of the measures or the incorporation of uncertainty effects) differs in some cases in the scenario analyses. The effects of inflation, which are the focus of only a few studies, need to be seen in this context, too. Obst et al. (2024) report slightly negative effects on German inflation, citing capacity underutilisation and weak economic development as the dominant channel in their scenario. Goldman Sachs (2024b) identifies small positive effects on inflation but looks only at the euro area as a whole.

US dollar is directly passed through to the prices of imports from all countries. By contrast, BbkM- DE takes account of the fact that only part of foreign trade is settled in US dollars. Accordingly, the direct rise in import prices is considerably lower in that model. ¹³⁾ The transmission of this impulse from import prices to consumer prices is likewise significantly weaker and more gradual in BbkM- DE. In addition, in NiGEM, quite strong second-round effects via wages occur relatively swiftly. This further increases inflation and ensures a fairly high persistence of the inflation effect. This effect is also present in BbkM- DE, but is weaker. ¹⁴⁾

The simulation calculations point to upside risks for inflation developments, although their extent is highly uncertain. Estimates using BbkM- DE, which reflects in quite significant detail the specific characteristics of the German economy, point to rather low effects. The strong inflation effects in the NiGEM simulations are likely to represent an upper limit. However, the estimates with NiGEM suggest that the pass-

¹³ According to Eurostat data for 2023, only around one-quarter of German exports outside the euro area and slightly less than one-half of imports from non-euro area countries are settled in US dollars. In addition, higher foreign prices are passed through to German import prices to a lesser extent in BbkM- DE than in NiGEM.

¹⁴ Conceptual differences between BbkM- DE and NiGEM are also evident here. In NiGEM, the immediate wage response to price changes is already significantly stronger than in BbkM- DE. In BbkM- DE, the pass-through of wage changes to prices is also estimated to be weaker than in NiGEM. For more on the pass-through of wage developments to price developments in Germany including simulation calculations using BbkM- DE, see also Deutsche Bundesbank (2019a).

through of exchange rate changes to consumer prices could also be significantly stronger than in BbkM- DE and other models. ¹⁵⁾ Together with the larger second-round effects via wages, the overall inflation effects in NiGEM are considerably higher than in BbkM- DE. Experience gained in the recent period of inflation also shows that large cost shocks can be reflected in consumer prices at a higher intensity than moderate increases in costs. ¹⁶⁾ Moreover, the exchange rate pass-through to consumer prices is likely to intensify in an uncertain macroeconomic environment and with rising inflation. ¹⁷⁾ Ultimately, this supplementary information illustrates that scenario analyses of this kind often produce a cross-model consensus on the real economic impact, while the inflation effects diverge much more strongly.

¹⁵ See Ortega and Osbat (2020).

¹⁶ See, for example, Cavallo et al. (2024).

¹⁷ See Carrière-Swallow et al. (2024).

A higher carbon price could increase inflation. This forecast assumes a decline in the carbon price in 2027 from the national price cap for 2026 (€65 per tonne of CO₂) to the target price cap of €59 per tonne when the European emissions trading system ETS2 is launched. As the ETS2 price will generally be formed on the market and the volume of allowances, including those released from the market stability reserve, is limited, it is possible that this cap may be exceeded. The assumed dampening effect on energy prices could therefore fail to materialise, or prices could even go up. Simulations suggest that, to achieve the climate protection targets, a greater reduction in emissions is needed than would appear achievable with the carbon prices planned thus far. ³³⁾ If the volume of ETS2 allowances were set in accordance with the target, this could result in a higher price despite use of the market stability reserve. Should ETS2 prices turn out to be markedly higher, this would increase inflation and tend to dampen economic output.

The structural changes in Germany and abroad could have an even greater impact on the German economy and dampen potential output more strongly than previously estimated. The quantification of this impact on the German economy and estimated potential output is subject to a high level of uncertainty. This forecast (like previous ones) already contains marked downward revisions of potential output, which could turn out later to have been too large. ³⁴⁾ Nevertheless, there is a risk that some of the structural problems will prove even more burdensome, or the adjustment processes even more lengthy, than currently expected. This would further diminish growth opportunities for the German economy and dampen the GDP outlook. For example, the weakness in productivity could last longer, the German export industry could benefit even less from growing sales markets, or private investment could decline more sharply still. Private consumption could then turn out to be weaker, as the labour market would probably experience greater cooling and wage growth would be lower. If the latter were to outweigh weaker productivity, this would also dampen inflation. In view of the low potential growth and possible large additional adverse shocks ahead, the German economy is closer to a recession – in the sense of an overall significant, longer lasting and broad-based decline in economic output, with persistent underutilisation of aggregate capacity.

³³ If the planned carbon price path remains unchanged and the energy efficiency gains over the past 30 years are extrapolated, the Bundesbank's model simulations from April 2024 conclude that emissions reductions will not meet the targets; see Deutsche Bundesbank (2024f).

³⁴ For example, if productivity were to be more positively affected by digitalisation than expected – say, through the use of artificial intelligence. Capital input could also turn out to be greater, e.g. due to higher investment in green technologies as part of the transition to a net-zero economy.

Financing costs for banks in Germany in the monetary policy interest rate cycle

Financing costs for banks in Germany in the monetary policy interest rate cycle

Financing costs for banks play an important role in the transmission of monetary policy. This is because changes in the cost of funding for banks generally lead to changes in bank lending rates. The tightening of monetary policy that began at the beginning of 2022 has also been reflected in higher financing costs for banks in Germany, in the form of rising market interest rates. In response to this, banks increased interest rates on bank loans. This was in line with the monetary policy objective of curbing lending in order to bring the excessively high inflation rate in the euro area back to the target level by reducing aggregate demand.

This article presents a financing cost indicator (FCI) for banks in Germany. The indicator combines the cost contributions by banks' various funding sources into a single metric. The prices of the funding sources are weighted by their share of the volume in the banks' financing mix. The indicator shows that the deposits of the private non-financial sector and banks' securitised liabilities have traditionally been the largest contributors, and remain so to this day.

The FCI of banks in Germany increased substantially during the most recent period of monetary policy tightening. Initially, there was a noticeable uptick in yields on securitised liabilities. Subsequently, it was chiefly the higher cost of deposits of the private non-financial sector that contributed to the rise in the FCI. As a result, in autumn 2023, the FCI reached its highest level in more than ten years.

A comparison with the FCI peak recorded in the period of monetary policy tightening in 2005 to 2008 shows that funding costs were not at unusually high levels when they reached their most recent high level. Despite a similarly high key interest rate level as in September 2008, the FCI was significantly lower in autumn 2023. The pace of the latest increase in the FCI was also not out of the ordinary given the rapid series of interest rate hikes. The differences in the levels are partly due to price factors. The onset of the global financial crisis in 2008 resulted in a massive increase in the cost of financing in money and capital markets. In addition, banks' financing structure changed. Securitised liabilities accounted for a significantly larger share of bank financing in the period leading up to the financial crisis than they did after-

wards. At the same time, the share in terms of volume of relatively low-cost deposits of the private non-financial sector was significantly lower prior to the financial crisis than it is now. Monetary policy and regulatory measures adopted after the financial crisis contributed significantly to these shifts in volume. In recent years, banks have once again increasingly availed themselves of the option of financing via money and capital markets. This development is likely to continue, given the final repayment in December 2024 of the funds taken up under TLTRO III and the scaling back of the Eurosystem's monetary policy portfolio.

1 Introduction

When banks grant loans, they usually have to finance them. To this end, banks can, for example, use deposits from households or enterprises or issue debt securities. The costs incurred by banks in this regard are a key factor in the pricing of their loans. ¹⁾ As a result, the cost of financing for banks is also of particular significance for monetary policy because changes in bank funding costs typically lead to changes in bank lending rates. In turn, the lending rates have an impact on the inflation rate via investment and consumption (seeChart 2.1).

Table 2.1: A stylised bank balance sheet

Assets	Liabilities and capital
Cash and cash balances at the central bank	Liabilities to the central bank
Credit	Deposits
Loans	of domestic banks
Securities ¹	of euro area households and non-financial corporations
	of central, state and local government of the euro area
	of other financial corporations of the euro area
	of non-residents ²
	Securitised liabilities (e.g. bank debt securities)
	Equity

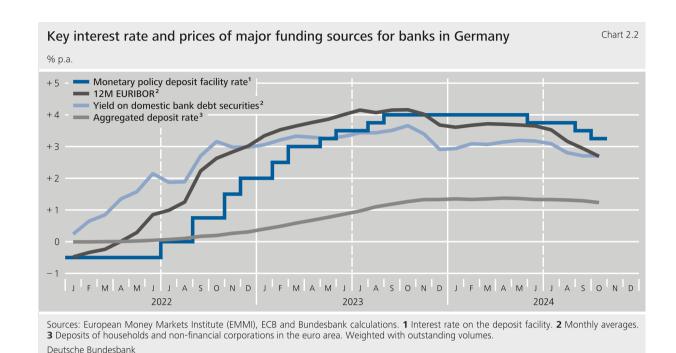

¹ Including equity and other shares.2 These include deposits by non-banks outside the euro area and deposits by banks outside Germany. Non-banks comprise non-financial corporations, households, non-profit institutions, central, state and local government and other financial corporations.

¹ See Deutsche Bundesbank (2023a).

The cost of financing for banks is a key element in the transmission of monetary policy due to the influence this has on bank lending rates. ²⁾ For the purposes of analysing and calibrating monetary policy, it is important to identify the factors that determine the cost of financing for banks and to monitor their development. Depending on the extent to which banks make use of the individual funding sources, monetary policy impulses may be transmitted by banks in a diluted or concentrated form, or in a delayed or accelerated manner. In addition to standard monetary policy, which primarily determines the cost of financing for banks in the shorter term, there are additional factors that have a long-term impact on the cost level and the structure of banks' financing mix. These include non-standard monetary policy measures as well as structural changes that concern regulatory requirements or the investment behaviour of economic actors, for example.

An individual bank has little room for manoeuvre when it comes to pricing some of its funding sources. Changes in the prices of these components are heavily influenced by monetary policy decisions, in particular changes in key interest rates. The series of key interest rate hikes that began in the euro area in July 2022 are reflected in higher prices for two of banks' main funding sources: Chart 2.2 shows that in 2022 and 2023, financing via both bank debt securities and the money market became noticeably more expensive. An individual bank can determine the extent to which it draws on these sources of financing. By contrast, it can do little to influence the price of this financing component.

² See Bank of England (2014).

With regard to the deposits of households and non-financial corporations, the influence of the individual bank on pricing depends on its market power. Depending on a bank's business model, the share of customer deposits in its financing mix can vary greatly. Whilst it is true that interest rates have also risen for customer deposits since 2022 because banks have raised them, the prices of these components rose to a much lesser extent and also at a later point in time than for the funding sources where banks have little room for manoeuvre in terms of pricing. However, there are limits to this room for manoeuvre, even in the case of deposits. When a bank sets its interest rates for deposits, it has to factor in a high degree of uncertainty regarding the volumes that will accrue to it. This is because they also depend on how competitors set their prices and on alternative investments.

A financing cost indicator (FCI) can be calculated to summarise the development of the costs of various sources of bank financing. ³⁾ In this context, it makes good sense to focus on the cost of debt financing. This is because capital costs constitute imputed costs. Although these can be derived from share price developments based on certain

³ Illes et al. (2015) also calculate this kind of indicator by determining funding costs as the volume-weighted average of the interest rates on new business and applying the shares of the respective balance sheet items in total assets as the volume weighting.

assumptions, only few banks in Germany are listed on the stock exchange (see the supplementary information on constructing an indicator for banks' financing costs). An FCI is made up of the relative weightings of the funding sources and their respective prices at a given point in time. This means it reflects the marginal financing costs at that point in time. Changes in the prices of large-volume funding sources have a comparatively strong impact on the development of the FCI. However, shifts in volumes between the funding sources also have an effect on financing costs overall. Over time, banks can, to a limited extent, exchange different funding sources for each another. If the price of one funding source rises disproportionately, banks often shift volumes towards more affordable forms of funding, to the extent that they are able to do so.

In the most recent period of monetary policy tightening in 2022 and 2023, the FCI rose swiftly and sharply and remained at an elevated level in 2024. The current FCI level and changes in it since the start of 2022 are discussed in parts 2 and a3 of this article. Supplementary information compares in greater detail the FCI of banks that are financed primarily by deposits with the FCI of banks that are financed more by market-based sources. Part 4 demonstrates that the FCI followed a different path during the most recent period of monetary policy tightening than it did during the period of tightening prior to the global financial crisis. What is behind the differences in the development of the FCI and its respective levels in the two periods? Part 5 provides answers to this question. The reasons for the differences can be found chiefly in the period between the two periods of tightening. This was, after all, a period shaped by monetary policy easing during the financial and the European sovereign debt crisis, as well as regulatory changes and a protracted period of negative interest rates. The article concludes by describing how the FCI has developed in 2024, when monetary policy began to ease the degree of restriction once more.

⁴ In contrast to this, an "average" FCI can also be calculated. See the supplementary information on the construction of the FCI.

Supplementary information

Constructing an indicator for banks' financing costs

In order to monitor and classify developments in banks' collective financing costs, the Bundesbank uses a financing cost indicator (FCI). The calculation is based, first, on information on the debt financing structure of the banking sector, i.e. the volumes of financing sources used. Second, information on current interest rates and yields on these funding sources is used. This comprises new business rates on various deposits and the yields on bank debt securities. The FCI for the banking sector presented here is calculated as the stock volume-weighted average of current interest rates and yields. This allows changes in the FCI over time to be attributed to price and volume changes.

The FCI presented in this supplementary information indicates the notional interest rate at which the banking system could refinance its existing liabilities afresh in the composition on a given reference date. It therefore measures the volume side based on stock variables, but the price side based on new business rates. There are various reasons why it makes sense to merge these disparate concepts. With regard to the volume side, it is assumed that banks are, at the current end, obtaining funding in line with the financing structure of the stocks of their outstanding liabilities and thus retain this financing structure. This assumption prevents the indicator from fluctuating strongly on a monthly basis if the volume shares of new business from individual financing sources vary significantly over time. If the relatively stable stock volumes are used to calculate the indicator, changes in the indicator can generally be interpreted as price signals in the short term. Volume shifts between funding sources only become apparent in the longer term using this calculation method.

As the price side is reflected by new business, this is an indicator of marginal financing costs. This approach makes sense because, in the monetary policy transmission context, the focus is on marginal financing costs – as opposed to average financing costs. This is because marginal financing costs form the basis for banks' lending decisions: in order to set their lending rates, banks compare the marginal costs of their financing with the potential income. Lending rates, in turn, impact on aggregate demand and thus also on inflation. Alternatively, and in the context of other questions, financing costs can also be calculated on the basis of the average interest rates for the

stock of individual financing sources. Such an indicator of average financing costs is useful for topics where past decisions also matter. One example is the topic of financial stability: previous financing and lending decisions are a major factor in banks' profitability. This, in turn, affects banks' resilience and, as a result, also financial stability as a whole.

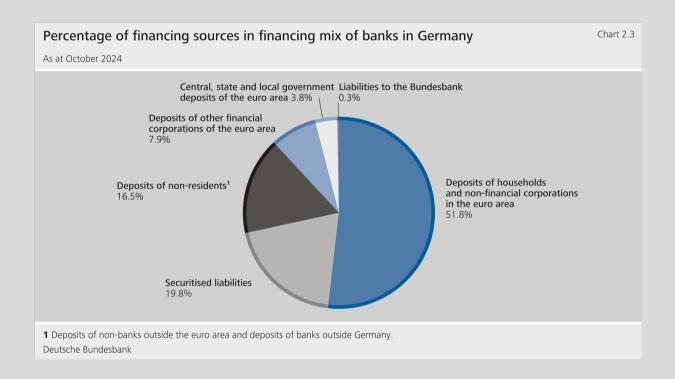

The FCI presented here is designed as a debt financing cost indicator and disregards the cost of equity; moreover, the FCI approximates financing costs rather than calculating them exactly. Capital costs are imputed costs and, unlike borrowing costs, cannot be observed directly. Under certain assumptions, they can be indirectly derived from share price movements. However, a large proportion of banks in the German banking system – especially the savings banks and cooperative banks, whose numbers make them a meaningful factor – are not listed on the stock exchange. Lastly, given the data available, the interest rates or yields on some financing positions can only be approximated by means of the prices of related financing instruments. For the FCI, this means that financing costs cannot be modelled precisely.

The monthly balance sheet statistics provide information on the financing structure of the German banking sector, i.e. the volume side of the FCI. ¹⁾ Only those positions that represent costs to the banking system as a whole are relevant for an indicator that is intended to model the banking sector's total debt financing costs. Interbank loans within the banking system under consideration balance each other out and are therefore disregarded. This is because they are a liability for the borrowing bank, but a claim for its respective counterparty. In aggregate terms, interbank loans therefore do not create costs for the banking system as a whole, but only create redistributions within the system. The same applies to liabilities arising from derivatives transactions with the banking sector. Derivatives liabilities to non-banks are negligible because of their small size and are therefore also omitted from the FCI.

Of the sources of debt financing included in the FCI, the deposits of euro area house-holds and non-financial corporations, as measured by volume, are most important for banks. Chart 2.3 shows that, in October 2024, time, savings and overnight deposits of the private non-financial sector accounted for more than one-half of the debt financing of the aggregate German banking system (51.8 %). Securitised liabilities accounted for just under 20 % of debt financing. These mainly comprise bank debt securities issued in the capital market (around 18 % of debt financing), but also short-term debt

¹ The balance sheet items(BSI) statistics are used for the euro area.

securities issued in the money market (1.6%). This was followed by deposits of non-residents ²⁾ (16.5%). Deposits of other financial corporations of the euro area, such as pension funds, insurance companies and other financial market players, accounted for nearly 8%, while those by central, state and local government of the euro area accounted for just under 4%. The German banking system's liabilities to the Bundesbank, including those arising from targeted longer-term refinancing operations (TLTROS), accounted for 0.3% of the German banking system's debt financing. In the euro area as a whole, the composition of banks' funding mix is very similar to that of Germany. ³⁾

For the price side of the FCI, interest rates and yields from the MFI interest rate statistics and the securities issues statistics as well as money market rates are used.

The MFI interest rate statistics record domestic banks' new business rates on deposits of households and non-financial corporations in the euro area. New business rates need to be approximated for deposits of other economic agents. These include deposits of central, state and local government, which are mainly short-term deposits.

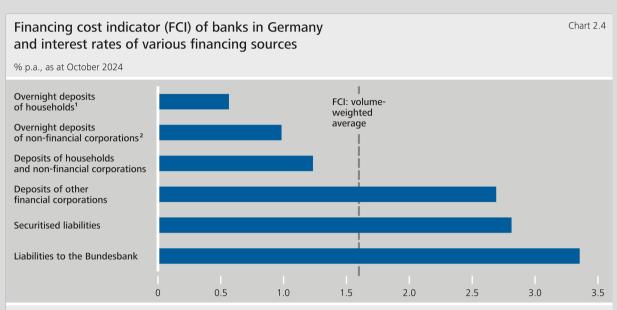

² These include deposits of non-banks outside the euro area and deposits of banks outside Germany. Non-banks comprise non-financial corporations, households, non-profit institutions serving households, central, state and local government, and other financial corporations.

³ Instead of liabilities to the Bundesbank, the FCI for the euro area includes the liabilities of euro area banks to the Eurosystem.

The interest rate on overnight deposits of households is applied to these funds. 4) The interest rate on deposits of non-residents is approximated using the interest rate on overnight deposits of enterprises. The choice of a short-term interest rate is motivated by the fact that non-residents' deposits are predominantly likely to constitute deposits of enterprises in order to settle their payments in euro. The average yield on secured and unsecured bank debt securities from the securities issues statistics is used as the yield on securitised liabilities. The main refinancing rate is used as the price for liabilities to the Bundesbank or the Eurosystem (excluding TLTROs), as the majority of banks' funding needs have traditionally been covered by main refinancing operations with the Eurosystem. That changed with the introduction of targeted longer-term refinancing operations(TLTROs). The TLTRO price is approximated using the Eurosystem deposit facility rate. The interest rate on liabilities arising from deposits of other financial corporations of the euro area is approximated using the 12-month EURIBOR. This choice is motivated primarily by the investment behaviour of other financial corporations. That is because their investment decisions are informed by more targeted yield considerations than those of the private non-financial sector. The choice of the 12month EURIBOR also reflects the fact that the deposits of other financial corporations break down evenly between original maturities of less than two years and those of more than two years.

The FCI is a volume-weighted average of prices for the various financing sources used by banks. The vertical line in Chart 2.4 shows the FCI at the end of October 2024. At that time, the FCI stood at just under 1.60 %. Deposits of households and non-financial corporations, at an interest rate of 1.2 %, particularly proved to be the most cost-effective source of financing. However, deposits of central, state and local government and by non-residents were also, in keeping with assumptions, relatively favourable sources of financing for banks. By comparison, issuance of securitised liabilities was relatively expensive. The yield was 2.8 %. For euro area banks as a whole, the picture is similar in terms of the prices of the various financing sources.

⁴ In principle, the interest rate on overnight deposits of non-financial corporations would also be conceivable as an approximation of the interest rate conditions for government deposits. In terms of their stability, however, government deposits are likely to be more comparable to household deposits in many cases, for example in terms of the consistency of inflows and outflows.

Deutsche Bundesbank

2 Composition of the FCI at the current margin

The level of banks' overall funding costs is derived from the sum of the prices for the individual funding sources – that is, their interest rates or yields. These are weighted using the share of the respective funding components in banks' overall financing. An FCI combines the respective prices and volumes into a single metric (see the supplementary information on constructing an indicator for banks' financing costs, which also provides a more detailed presentation of the individual funding sources). This makes it possible to calculate the contributions by the individual funding sources to the overall financing costs. This is done by multiplying the prices of each funding source by its volume share in the financing mix. Viewed in isolation, the share of a funding source in the cost of financing for banks therefore rises when it becomes more expensive and /or is increasingly utilised. Chart 2.5 illustrates the contributions by the individual sources to the FCI at the end of October 2024. The FCI of banks in Germany stood at 1.60 % at this time.

Deutsche Bundesbank

Historically and to date, two funding sources have been particularly relevant to the cost of financing for banks in Germany: deposits of the private non-financial sector (households and non-financial corporations) in the euro area, and securitised liabilities. Taken together, these two funding sources currently account for more than twothirds of the cost of financing for banks in Germany as reflected in the FCI. In this context, the significant contribution made by deposits is due more to their major share in banks' financing mix than to high interest rates on deposits. They currently account for somewhat more than half of the total volume of all funding sources included in the FCI. Deposits of households in particular are an attractive source of funding for banks. Given that these deposits are largely covered by deposit insurance, households accept a relatively low rate of remuneration. This means that banks can offer low interest rates on household deposits, 5) as illustrated in Chart 2.4 in the supplementary information on constructing the FCI. By contrast, deposits of non-financial corporations are somewhat more costly for banks, in part because the higher volume of such deposits often means they are not fully covered by deposit insurance. The average yield on banks' securitised liabilities, which, for the purposes of calculating the FCI, includes long-term bank debt securities and short-term money market debt securities, is relatively high by comparison. Although banks are, on the one hand, rate takers in respect of these funding sources, on the other hand, this enables banks to raise larger sums on the market guickly and in a manner that is easy to calculate. It is not possible to achieve this to a comparable extent with deposits. Although securitised liabilities come at a high price, the contribution they make to the financing mix is currently lower than that of deposits, given that they account for a smaller share of the financing mix. Their volume share at the end of October 2024 stood at somewhat below 20%.

Other components with a significant impact on the level of the FCI comprise deposits of other financial corporations of the euro area and deposits of non-residents. ⁶⁾ The relevance of deposits of other financial corporations to the FCI, such as pension funds or insurance companies, is based on the fact that, at present, these deposits are comparatively expensive. ⁷⁾ By contrast, the contribution of deposits of non-residents is primarily due to their sizeable, near 17 % volume share in banks' financ-

⁵ First, banks have a certain power when it comes to setting prices, especially for households. Second, the bulk of the deposits consists of overnight deposits, which are held more for liquidity rather than for investment purposes, meaning that yields play a less important role for households than in the case of alternative investments. See Deutsche Bundesbank (2023a).

⁶ Deposits of non-banks outside the euro area and deposits of banks outside Germany.

⁷ The price of this FCI component is approximated using the twelve-month EURIBOR. This stood at 2.5 % at the end of October 2024.

ing mix. Conversely, the deposits of central, state and local government of the euro area and banks' liabilities to the Bundesbank are of only minor relevance to the level of the FCI. The reason for this is that both funding sources only account for a comparatively small volume and therefore do not play a significant role in banks' financing mix.

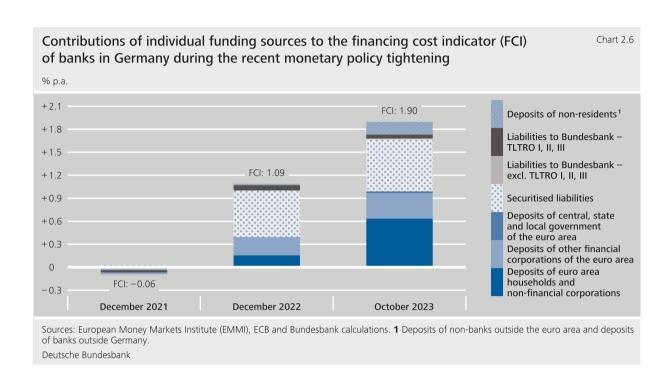

In the euro area, the FCI stood at 1.68% at the end of October 2024, and was therefore somewhat higher than in Germany (see Chart 2.5). The higher funding costs for banks in the euro area are due mainly to the fact that banks in the euro area were obliged to pay higher average yields for their securitised liabilities than banks in Germany. By contrast, there were no notable differences in the volume shares of the individual funding sources.

The level of the FCI and the relevance of the various funding sources to overall financing costs are subject to change over time. The level of the FCI in Germany and the euro area is currently significantly higher than it was just three years ago at the end of the negative interest rate period. In the interim, increases in key interest rates in particular have led to changes in the cost of financing.

3 The cost of financing for banks during the period of monetary policy tightening in 2022-23

The change in course in monetary policy adopted by the ECB Governing Council brought about a substantial increase in the FCI as of end-2021. In response to the sharp rise in inflation across the euro area, the ECB Governing Council began a series of interest rate increases in July 2022. By September 2023, ECB Governing Council had swiftly raised key interest rates by a total of 450 basis points in ten consecutive increments. This resulted in the deposit facility rate reaching its highest level since the euro was introduced in 1999. At the end of September 2023, the main refinancing operations rate had climbed to its highest point in over 20 years, reaching a level last seen in August 2001. After the FCI stood at -0.06 % at end-2021, only slightly higher than its historical low, it also edged up in the wake of the interest rate increases. The pace of the increase in the FCI remained noticeably lower than the rapid increases in key interest rates. The upward trend in the FCI began as early as the start of 2022. This was because the ECB Governing Council had signalled a change in course as early as December 2021, 8) triggering a rise in market interest rates. This rise initially affected longer-term interest rates and, consequently, also the components of the FCI with longer interest rate fixation periods, most notably the yields on bank debt securities. This was followed by money market rates over the course of 2022, and subsequently also the components of the FCI with a shorter interest rate fixation period. In addition, banks started to adjust their interest rates on customer deposits. Within less than two years, the FCI had risen to 1.90 % by the end of October 2023, thus reaching its highest level since April 2011. With the majority of market participants expecting key interest rates to be reduced again as of November 2023, longer-term interest rates also began to decline, whereupon the FCI also fell again.

⁸ On 16 December 2021, the ECB Governing Council announced a step-by-step reduction in net asset purchases under the purchase programmes; see European Central Bank (2021). In addition, the targeted longer-term refinancing operations (TLTRO III) were discontinued after the tenth and final operation was allotted in December 2021.

The sharp rise in yields on securitised liabilities was the main driver of the increase in the FCI until around the end of 2022 (see Chart 2.6). The average yield rose by over 300 basis points in the period between end-2021 and end-2022. While securitised liabilities were not the most important source of funding for banks in terms of volume, they remained a significant component of the financing mix, accounting for almost one-fifth of the volume of all funding sources included in the FCI. Securitised liabilities accounted for the largest share of the increase in the FCI in 2022 as a result of their high volume and the sharply higher yields. This is particularly evident when the FCI is calculated separately for different bank financing models (see the supplementary information on the evolution of banks' funding costs under different financing strategies). In 2022 the FCI rose primarily among the types of institutions for which financing via financial markets is of particular importance. These consist chiefly of commercial banks and the central institutions of network systems (Landesbankenand DZ Bank). By contrast, the FCI of the primary institutions in network systems (that is, savings banks and credit cooperatives) increased only slightly at first. This is because they are financed largely by deposits.

However, rising interest rates on the deposits of other financial corporations and the private non-financial sector in the euro area also made a substantial contribution to the increase in the FCI by the end of 2022. The interest rate on deposits of

other financial corporations is approximated using the twelve-month EURIBOR. This rose significantly in 2022 and even exceeded the increase in yields on securitised liabilities. However, deposits of other financial corporations played a much smaller role than securitised liabilities in terms of volume in the period under review. Consequently, its contribution to the increase in the FCI is ranked second, behind that of securitised liabilities. The third largest contribution stemmed from the deposits of households and non-financial corporations in the euro area. Banks were hesitant about raising their interest rates on such deposits until the end of 2022. The increase in the aggregated interest rate was mainly driven by rising interest rates on time deposits. By contrast, interest rates on overnight deposits and savings deposits barely increased and remained around zero, as had been the case during the low interest rate period. ⁹⁾ In 2022, however, the deposits of the private non-financial sector accounted for the highest weighting in the FCI, amounting to an average volume share of just under 50 %. Consequently, even the minimal increase in the aggregated interest rate on deposits resulted in a notable increase in the FCI.

The other funding sources for banks had a minor impact on the increase in the FCI in 2022. This is because either their volumes were relatively low or price increases were still restrained. The price of the TLTROs, in which the deposit facility rate is applied, rose sharply by 250 basis points during the period under review. However, funds taken up under the TLTROs accounted for only a small share of banks' financing mix in 2022, not least because repayment of these funds had already begun. ¹⁰⁾ Similarly, the deposits of non-residents and the deposits of central, state and local government of the euro area had barely any effect on the increase in the FCI in 2022.

Developments in the FCI from the beginning of 2023 to October 2023 were shaped by a significant increase in the cost of financing via deposits of the private non-financial sector in the euro area, as well as deposits of non-residents. The main reason for the increase in the price of deposits of the private non-financial sector was the sustained rise in interest rates on time deposits. This is because banks had raised them

⁹ The pass-through of interest rates on time deposits is usually swift and virtually complete because time deposits are in competition with other longer-term investment options. By contrast, overnight deposits are held principally for payment as opposed to investment purposes. The pass-through of interest rates on these deposits is both sluggish and incomplete. Bundesbank analyses show that during the period of monetary tightening, banks passed on the increase in market interest rates to overnight deposits to a lesser extent than historical correlations would suggest. One reason for the weaker-than-expected interest rate pass-through could be an asymmetric interest rate pass-through that is dependent on the stage in the interest rate cycle. Another reason could be the significantly higher volume of these deposits. See Deutsche Bundesbank (2023a).

¹⁰ Bank liabilities to the Bundesbank excluding funds taken up under the TLTROs made barely any contribution to the increase in the FCI. As assumed, the price of these liabilities was approximated using the main refinancing rate. Although this rate rose by 250 basis points, at 0.1 % their average volume share was marginal.

significantly by the autumn. In addition, banks were now also paying somewhat higher rates on overnight deposits and savings deposits, having initially raised interest rates on these deposits only to a very limited extent in 2022. 11) Moreover, the private non-financial sector was now increasingly reallocating funds away from lower-interest overnight deposits towards higher-interest time deposits. These three effects resulted in an increase of almost 1 percentage point in the aggregated interest rate across all deposit types over this period. At the same time, at around 50 %, the volume share of deposits of the private non-financial sector remained virtually as high as before because any volume shifts in banks' financing mix largely took place only between the various types of private non-financial sector deposits. All in all, more than half of the increase in the FCI during this period can be attributed to interest rate increases on these deposits and, consequently, to price effects. The increase in deposit interest rates was especially noticeable in the funding costs of the primary institutions of network systems, where funding is heavily dominated by deposits. In the first nine months of 2023, the FCI for these institutions quadrupled (see the supplementary information on the evolution of banks' funding costs under different financing strategies). The price of deposits of non-residents also rose markedly in response to the sustained increase in the twelve-month EURIBOR. However, their contribution to the increase in the FCI was much smaller than the contribution by the deposits of the private non-financial sector due to their lesser importance as a source of funding.

The remaining components of the FCI made a negligible contribution to its overall development in 2023. The main reason for this is that – unlike customer deposits – the majority of the price increases in the remaining components of the FCI had already occurred in 2022. Following the marked increase in yields for securitised liabilities in 2022, 2023 saw yields rise only slightly up to the end of October. The decline in inflation rates in the euro area during the course of 2023, and the accompanying mounting expectations among market participants that interest rates would be cut are likely to have been the main reasons for the modest rise in yields.

Funding costs also rose significantly in the euro area as monetary policy was tightened. The funding sources that contributed significantly to the increase in costs were

¹¹ The rise in the heterogeneity of interest rates on overnight deposits across all banks and the fairly substantial interest rate hikes by individual banks indicate that competition for deposits intensified (see Deutsche Bundesbank (2023a)).

the same as those in Germany. In addition, euro area banks operating in the deposit business with the private non-financial sector likewise only passed on the increase in key interest rates with a significant time lag.

Supplementary information

The evolution of banks' funding costs under different financing strategies

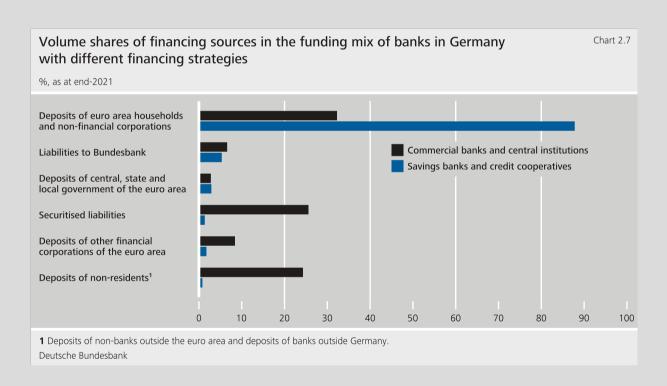

The German banking system is dominated by two types of financing strategy: traditional deposit-based funding (retail funding) and mixed financing consisting of a combination of customer deposits and capital market funding (retail and wholesale funding). The first of these is principally employed by the primary institutions of the network systems, i.e. savings banks and credit cooperatives. Their main source of funding is the traditional avenue of customer deposits from households and firms. The other banks in the German banking system also source funding from institutional depositors and the capital market. These include primarily the private commercial banks looked at in this article (big banks and regional banks) and the central institutions of the network systems.

Banks' pricing power varies across the different funding sources: does this manifest in differences in the way the FCI evolves depending on the financing strategy employed? According to the literature, competition in the banking sector is imperfect. In Germany, this is probably because many banks are firmly anchored in a specific region and this breeds high customer loyalty. Linked to this is the degree of interest rate elasticity applying to demand for banking products, in other words whether even small interest rate differences are enough to prompt customers to shift their financial resources into alternative investments or not. ¹⁾ As far as financing through deposits of households and non-financial corporations is concerned, banks do, therefore, wield a certain amount of pricing power. In 2022-23 this came to the fore in banks' hesitant approach to adjusting the interest rates on households' and non-financial corporations' deposits to the higher interest rate environment. By contrast, when it comes to financing via the money and capital markets, banks tend to act more as price takers. As described in the main text, yields for market-based forms of financing tracked monetary policy tightening with little time lag. Based on these differences and the

¹ See Deutsche Bundesbank (2023a).

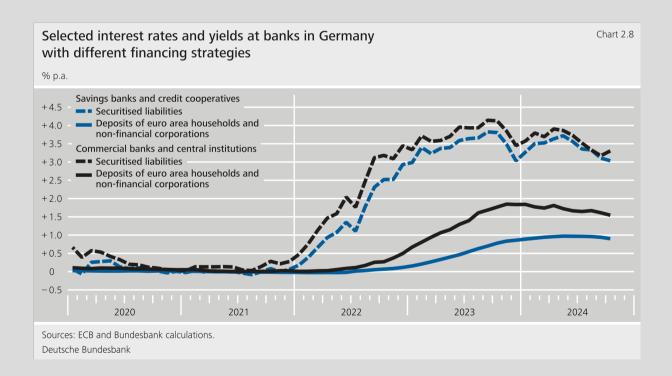

different financing strategies, the question arises as to the extent to which the funding costs of savings banks and credit cooperatives have differed from those of other banks in the time since 2022.

The primary institutions of the network systems (i.e. savings banks and credit cooperatives) draw most of their funding from deposits of the private non-financial sector (see Chart 2.7). ²⁾ These banks are chiefly in the business of lending to non-financial corporations and households, with deposits by those actors making up the majority of the other side of their bank balance sheet. At the end of 2021, shortly before monetary policy began to be tightened, deposits from the euro area private non-financial sector accounted for just under 88% of the funding mix considered in the FCI metric at savings banks and credit cooperatives. Deposits from non-residents and other financial institutions amounted to less than 3%. The share of market-based financing via securitised liabilities was only slightly over 1% since, in both network systems, issuance is largely the preserve of the central institutions.

² The central institutions (Landesbanken and DZ Bank in its role as the central institution of the credit cooperatives) are counted as belonging to the category of other banks in this analysis: they make heavy use of market-based financing instruments as well, not least in their function as central institutions of their respective network.

By contrast, the other banks in Germany, i.e. commercial banks and the central institutions (of the savings bank and credit cooperative network systems), rely on a broader funding mix. Financial market innovation, financial integration and the wave of deregulation in the 1990s opened up market-based business areas and forms of financing, which were mainly tapped by large and multinational banks. 3) A hallmark of this is the substantial role played by bank debt securities in the funding of commercial banks and central institutions; these made up more than 23 % of the funding mix at the end of 2021. Market-based financing instruments (securitised liabilities) also include short-term debt securities in the money market, which accounted for slightly more than 2% of the combined commercial bank and central institutions' funding mix at the end of 2021. These institutions therefore had a significantly higher proportion of all marketbased financing in their funding mix than the savings banks and credit cooperatives, at just under 26%. Deposits from euro area households and non-financial corporations made up 32 % of the funding mix, playing a much smaller role than for the savings banks and credit cooperatives. That said, the other banks also drew on funding from deposits of non-residents (24%) and deposits of other financial corporations of the euro area (8%) to a greater extent.

³ See Deutsche Bundesbank (2015).

From the beginning of 2022, average yields on securitised liabilities rose at all banks. For commercial banks and central institutions this form of financing is systematically more expensive than for savings banks and credit cooperatives (see Chart 2.8). ⁴⁾ Overall, yields on securitised liabilities tracked monetary policy tightening with little delay at all banks. Since the end of 2023, average yields at German banks have ranged between 3% and just over 4%. For the savings banks and credit cooperatives, funding via securitised liabilities is generally somewhat cheaper. One reason for this is likely to be the existence of their own institutional protection schemes. These are designed to aid member institutions that are experiencing economic distress by safeguarding them from insolvency and liquidation.

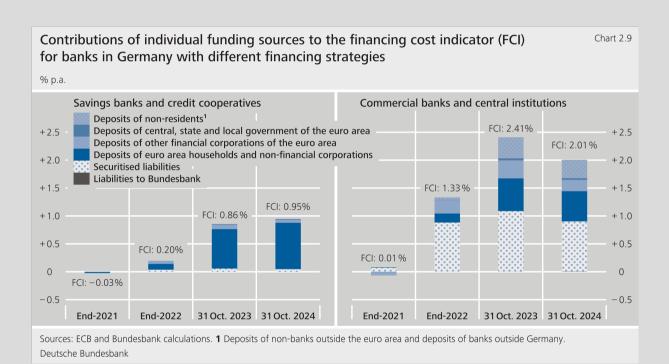

The average interest rate applied to deposits of households and non-financial corporations rose more strongly at commercial banks and central institutions than at savings banks and credit cooperatives; it also went up earlier. Chart 2.8 shows that interest rates on private non-financial sector deposits were still close to zero at both types of institution until mid-2022. 5) Commercial banks and central institutions began raising their deposit rates in the second half of 2022. To compete with other banks, they may have sought to retain or attract deposits from interest-sensitive customers by offering higher interest rates. One incentive to do so was that this source of financing still remained cheaper for them overall than funding through securitised liabilities. However, when it comes to competition for deposits and to pricing power, savings banks and credit cooperatives are likely to have benefited from their pronounced regional ties and high customer loyalty. As a result, they were much slower to raise interest rates than the other banks and increased them less overall. This meant that in 2023 funding via deposits from households and non-financial corporations was up to 1 percentage point cheaper for savings banks and credit cooperatives than for the other banks. The interest rate spread narrowed of late, to around 70 basis points.

Different financing structures and the fact that prices for market and deposit-based funding sources went up at different times combined to make funding costs diverge depending on financing strategy as early as 2022. When the negative interest rate policy period came to a close at the end of 2021, funding costs for both types of institution were near zero. However, they started to diverge as soon as monetary policy tight-

⁴ Yields on securitised liabilities are calculated using data from the Centralised Securities Database(CSDB) since the capital market statistics do not publish yields broken down by the categories of bank examined here.

⁵ Deposit rates responded to monetary policy tightening later than yields on market-based instruments. This pattern is likely to stem from the asymmetrical transmission of monetary policy stimuli to deposit rates. Deposit rates respond more strongly when policy rates are falling, and more weakly when policy rates are on the rise (see Deutsche Bundesbank (2023a)).

ening got under way. While savings banks and credit cooperatives' funding costs increased only marginally to 0.20% over the course of the year, funding costs at other banks climbed significantly to 1.33% (see Chart 2.9). Funding via securitised liabilities was the biggest contributor to that increase, mainly due to the larger role that this avenue of funding plays for commercial banks and central institutions. However, deposits of other financial corporations of the euro area (which are assumed to be remunerated at the 12-month EURIBOR in the FCI) also grew more expensive up to the end of 2022. By contrast, the slightness of the increase in funding costs at savings banks and credit cooperatives stems from the fact that their funding mix is dominated by private non-financial sector deposits and banks barely raised interest rates on those in 2022.

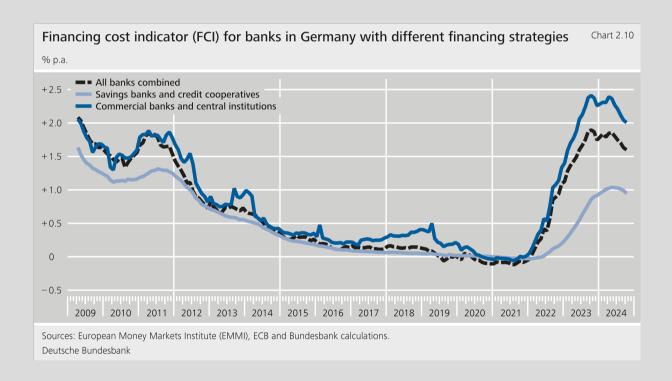

Between the beginning of 2023 and the end of the tightening cycle in 2023, the funding costs of both types of institution went up chiefly because the costs for deposits from households and non-financial corporations increased; however, higher costs for deposits by non-residents at commercial banks and central institutions drove a further divergence in funding costs. The increase in funding costs over the course of 2023 for both types of institution is primarily attributable to the significant rise in interest rates on deposits from households and non-financial corporations. This resulted in funding costs at savings banks and credit cooperatives hitting 0.86 % in October 2023. Deposits by households and non-financial corporations accounted for a smaller share of the funding mix at commercial banks and central institutions than was

the case for savings banks and credit cooperatives. That said, with commercial banks and central institutions raising their interest rates on such deposits more strongly than savings banks and credit cooperatives did, this financing component pushed up their costs significantly, too. On top of that, they draw a greater proportion of their funding from deposits by non-residents (which are assumed to be remunerated at the interest rate on overnight deposits of euro area non-financial corporations for the purposes of the FCI) than savings banks and credit cooperatives. The increased cost of those fuelled the increase in funding costs for commercial banks and central institutions. At the end of October 2023, their funding costs amounted to 2.41 %. Ultimately, the difference between the funding costs of the two types of institution increased from 1.13 percentage points at the end of 2022 to just under 1.55 percentage points.

Since October 2023, funding costs at commercial banks and central institutions have fallen. By contrast, savings banks and credit cooperatives' funding costs have continued to rise, with the gap between the funding costs of both types of institution narrowing as a result. The smaller difference was driven by a decrease in medium to long-term yields on securitised liabilities. After the last rise in key interest rates in September 2023, yields from October 2023 onwards anticipated financial market participants' expectations of interest rate cuts. As a result, the funding costs of commercial banks and central institutions, who rely to a greater extent than savings banks and credit cooperatives on securitised liabilities for funding, fell to 2.01 % at last count. Meanwhile, savings banks and credit cooperatives carried on slowly but steadily raising the interest rates they paid to private non-financial sector depositors. Competition for deposits likely intensified the longer that monetary policy tightening lasted, placing those banks, too, under increasing pressure to adjust their deposit rates. Since October 2023, savings banks and credit cooperatives' funding costs have risen to 0.95 % at last count. The gap between the funding costs associated with the two strategies thus stood at 1.06 percentage points.

Another major difference concerns the volatility of the funding costs of the two institution types, which is higher for commercial banks and central institutions than for savings banks and credit cooperatives due to the former's more market-based approach to financing. Chart 2.10 shows the long-term evolution of the financing cost indicators for both types of institution. Comparing the FCIs reveals that the funding costs of commercial banks and central institutions are subject to greater fluctuations. This is because market-based funding figures more prominently in their funding mix, which means that volatility in the money and capital markets is more strongly reflected in the FCI of commercial banks and central institutions. Conversely, volatility in the money and capital markets cannot impact the FCI of savings banks and credit coopera-

tives to the same extent, as they obtain more of their funding from deposits. Accordingly, savings banks and credit cooperatives can reap more of the benefits of the pricing power that banks (regardless of institution type) exercise when setting prices for deposits of households and non-financial corporations. This pricing power allows banks to make relatively steady adjustments to their deposit rates. As a result, the FCI of savings banks and credit cooperatives, with their highly deposit-based financing structure, is rendered less volatile. However, the savings banks and credit cooperatives also benefit in another way, as the adjustments to their deposit rates do not necessarily have to track the movements of market interest rates one-to-one. In this sense, the high proportion of deposits in their financing structure effectively shields their capital from the impact of interest rate risk. ⁶⁾

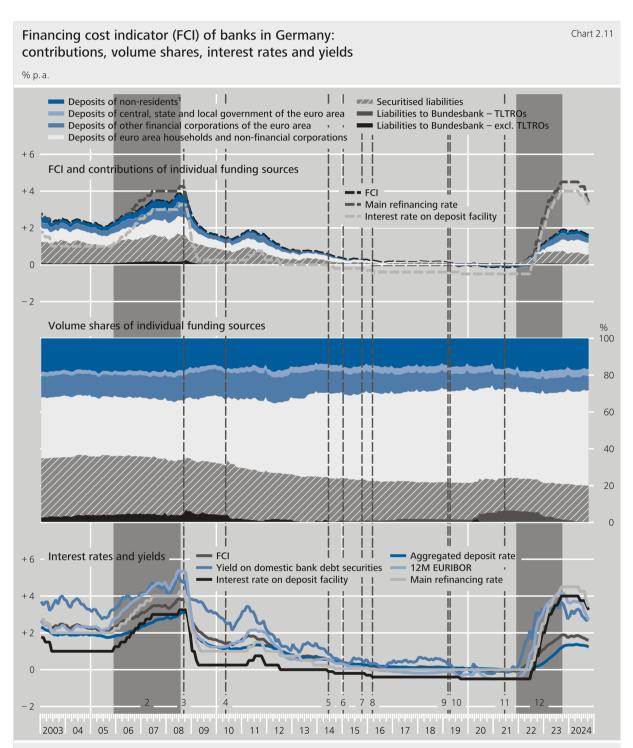

⁶ See Drechsler et al. (2021).

4 Comparison with developments in the 2005 to 2008 period of monetary policy tightening

For monetary policy, the question is whether banks' funding costs in autumn 2023 were at a level that was appropriate, given the intended restrictive effect of monetary policy. This is because the level of banks' funding costs influences the general funding costs for the private non-financial sector via transmission to lending rates, and therefore ultimately also inflation (see Chart 2.1). Indications as to whether the level of funding costs, as measured by key interest rate hikes, was exceptionally high can be obtained, for example, by comparing it with the development of funding costs during the last period of significant monetary policy tightening between 2005 and 2008 (see Chart 2.11). 12)

¹² Apart from the period of tightening in 2022-23, there have been two additional periods of tightening since the single currency was introduced, both of which saw key interest rates at a comparable level when the series of interest rate hikes came to an end. The first period began in November 1999 and ended in 2001. However, a comparison with this period of tightening is not possible because the FCI time series does not begin until 2003. The second period began in December 2005 and ended in July 2008.

Deutsche Bundesbank

The FCI rose significantly between 2005 and 2008. In addition to monetary policy tightening, the global financial crisis also had an impact on the FCI as of 2008. The reason for the tighter monetary policy in 2005 was the same as in 2022: excessive inflation. However, because there was a much smaller deviation from the price stability objective than in 2022, the tightening of monetary policy was not as rapid or as pronounced as in 2022-23. In the period between December 2005 and September 2008, the ECB Governing Council increased key interest rates by 225 basis points in a series of nine steps. The onset of the financial crisis also coincided with a considerable increase in interest rates and yields, partly on account of elevated risk spreads. The FCI also increased significantly during this period. In September 2008, the FCI reached what remains its highest ever level of 3.85 %. It had stood at 2.06 % before beginning to rise in September 2005. This means that the 179 basis point increase in the FCI in the 2005 to 2008 period was similarly significant as the 196 basis point increase in 2022-23.

13) However, it should be noted that the increase in 2005 to 2008 was spread over a period that was more than twice as long as the recent one.

A comparison with the peak reached by the FCI in the first period of tightening shows that funding costs did not reach exceptionally high levels in autumn 2023 despite the sharp increase in key interest rates in 2022-23. On the contrary, compared to the key interest rate level, they even appear to be fairly low. The main refinancing rate, the relevant rate for monetary policy at the time, stood at 4.25 % in September 2008, which is at a similarly high level (4%) to the rate for the deposit facility, currently the relevant rate for monetary policy, in autumn 2023. At the same time, however, at 190 basis points, banks' funding costs in October 2023 were significantly lower than in September 2008. This was partly due to the fact that the prices of the key components of the FCI (deposits of private non-financial sector in the euro area, securitised liabilities, deposits of non-residents) in October 2023 were lower than when the financial crisis began in September 2008. Furthermore, the banking system had a different financing structure in 2008 (see Table 2.2). This structure featured a relatively high weighting of comparatively expensive funding sources. For instance, the volume share of securitised liabilities in the period leading up to the financial crisis was more than one and a half times higher than in previous years. Also, the comparatively costly

¹³ The FCI also rose in 2011 on the back of interest rate increases. However, these rate hikes occurred only briefly, over a period of four months, and at 50 basis points, the increases themselves were modest. The increase in the FCI was similarly low.

deposits of other financial institutions used to play a larger role at that time. By contrast, the relatively low-cost deposits of households and non-financial corporations in the euro area played a significantly smaller role in the financing mix. ¹⁴⁾

Table 2.2: Development of interest rates/yields and of the volume shares of various funding sources of banks in Germany

	Interest rates/yields (% p.a.)			Volume share of FCI (%)		
Item	Sep. 2008	Oct. 2023	Spread (percent- age points)	Sep. 2008	Oct. 2023	Spread (percent- age points)
Deposits of euro area households and non-financial corporations	3.10	1.27	- 1.83	31.9	50.1	18.2
Deposits of other financial corporations of the euro area	5.38	4.16	- 1.22	13.4	8.0	- 5.4
Deposits of central, state and local govern- ment of the euro area	2.05	0.56	- 1.48	2.8	4.2	1.4
Securitised liabilities	4.86	3.55	- 1.31	29.0	19.1	- 9.9
Liabilities to Bundes- bank – excl. TLTROs	4.25	4.50	0.25	5.1	0.3	- 4.8
Liabilities to Bundes- bank – TLTROs	3.25	4.00	0.75	0.0	1.3	1.3
Deposits of non-residents ¹	2.58	0.97	- 1.61	17.8	17.1	- 0.7

However, funding costs in 2023 still appear to be low even after adjusting the interest rates and yields in 2008 for the effects of the financial crisis. Given the exceptional increase in the price components of the FCI as a result of the financial crisis, the values for 2008 are distorted and only partially suitable as a basis for comparison. Therefore, to obtain a more meaningful comparison, it makes sense to replace the 2008 price components with values that were not impacted by the financial crisis. Given

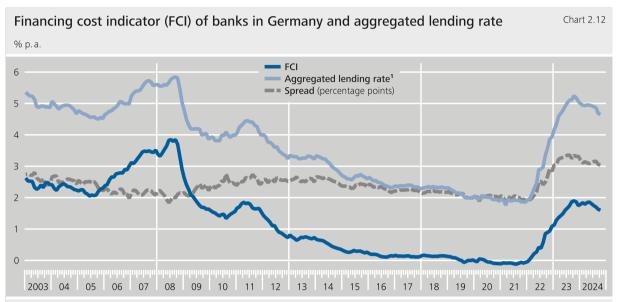

¹⁴ The reasons for the change in banks' funding structure are discussed in the next part of the article.

the similarity in key interest rate levels in 2008 and 2023, it stands to reason to apply the interest rates and yields for October 2023 and combine them with the volumes from September 2008. The notional FCI for September 2008 calculated using this method is 2.41 % (and therefore higher than the FCI for October 2023, which stood at 1.90 %). This means that current funding costs are lower even after "adjusting for" the high interest rates and high yields in 2008. The main reason for this is the shift in volumes in banks' financing mix towards more affordable sources of funding in the period between 2008 and 2023.

The fact that the level of bank funding costs in 2023 is lower than in 2008 also had a positive impact on their earnings situation. 15) While average interest expense (as a ratio of total assets) rose significantly in the German banking system, much like the FCI, during the most recent period of monetary policy tightening, interest expense (as a ratio of total assets) in the German banking system in 2023 was only just over half of what it was in 2008. And that was despite key interest rates being roughly equally high at both points in time. Even with the recent increase, banks' relatively low funding costs have had a positive impact on their earnings situation. Net revenue from interest-based business, for example, was up 10 % on 2008. This positive effect also becomes obvious when the FCI, which constitutes a weighted average of the prices on the liabilities and capital side of the bank balance sheet, is compared to a corresponding figure on the assets side: the aggregated lending rate ¹⁶⁾ is the price banks charge for their most significant earnings component. The difference between this interest rate and the FCI remained stable between 2003 and 2022, consistently ranging between 2 % and 3 % (see Chart 2.12). Since the start of 2023, this difference has exceeded 3 percentage points for the first time. This is because the FCI rose to a much lesser extent than the aggregated lending rate. The increase in this difference also reflects the fact that the FCI is currently relatively low against the backdrop of the current interest rate level.

¹⁵ See Deutsche Bundesbank (2024). In principle, changes in banks' funding costs only have an impact on interest expense following a certain delay because of what can sometimes be lengthy interest rate fixation periods. The interest expense is recognised in the banks' income statements and calculated on the basis of outstanding volumes and interest rates. In particular, rapid price changes in new business, such as the decline in interest rates during the financial crisis and the rise in interest rates in 2022-23, have a direct impact on the FCI, while the income statement is initially only affected to a limited extent since it focuses on the bank's overall business, and not solely on new business.

¹⁶ Calculated analogously to the FCI as the average of the aggregated new business interest rates for loans to non-financial corporations, consumer credit to households and housing loans to households, weighted by outstanding volumes.

Sources: European Money Markets Institute (EMMI), ECB and Bundesbank calculations. 1 Bundesbank calculations based on MFI interest rate statistics and monthly balance sheet statistics. Loans by banks in Germany to households and non-financial corporations. Weighted with outstanding volumes. Deutsche Bundesbank

Similarly, banks' funding costs in the euro area, as measured by the level of key interest rates, were not exceptionally high in autumn 2023. At the end of October 2023, they reached 1.97 %, their highest level in more than 11 and a half years. This was similar to the level in April 2009 (starting point of the time series for the euro area). ¹⁷⁾ However, key interest rates in autumn 2023 were significantly higher than they had been back then because in April 2009, the majority of the key interest rate cuts had already been implemented. The fact that, measured in terms of key interest rate levels, funding costs were not higher in 2023 is due largely to the fact that – as in Germany – the share of the funding mix attributable to deposits of the private non-financial sector was substantially higher in autumn 2023. In addition, these were remunerated at very low interest rates. At the same time, as was also the case for banks in Germany, the share of the now more expensive funding via securitised liabilities was smaller in previous years than it was at that time.

The weaker increase in the FCI in 2022-23 as compared to 2008 can be explained by structural changes. The financial crisis, coupled with the previous monetary policy

¹⁷ The Centralised Securities Database (CSDB) time series used in the pricing of the securitised liabilities of euro area banks does not start until April 2009.

tightening, was largely responsible for the FCI rising to such a high level in 2008. Both factors pushed the FCI up, especially on the back of short-term interest rate and yield increases. But why did the FCI in 2023 end up so far below the level in 2008, especially since the extent and pace of monetary policy tightening in 2022-23 were unprecedented in historical terms? While the financial crisis intensified the rise in the FCI in 2008, there were a number of factors in 2022-23 that had a structurally dampening effect on the increase in the FCI. In the next part of this article, the effects of the financial crisis, monetary policy and other factors on the difference in the level of the FCI in 2008 and 2023 are examined in more detail. It not only explains the reasons for changes in prices, but also why the structure of banks' financing mix has changed.

5 The FCI in 2008 and 2023: structural differences and their causes

In addition to standard monetary policy – that is, adjustments to key interest rates, which have a short-term impact on the FCI – there are other factors that shape its development. These factors may be short-term or long-term in nature and may either raise or dampen the level of the FCI. The global financial crisis had an impact on the FCI over a relatively short period of time, but this impact stemming from increased risk premia was highly significant. By contrast, non-standard monetary policy measures had the effect of dampening the FCI over a fairly long period. On the volume side, other factors of a structural nature impacted the FCI level by affecting how funding was composed, especially the shares of deposits and securitised liabilities in the financing mix. These volume-based factors had the effect of almost exclusively dampening costs in the FCI in the period observed here (see Chart 2.11).

The global financial crisis was the main factor that drove funding costs to a record high in 2008. Mistrust among financial market participants increased dramatically after the subprime crisis spilled over into the money market in the summer of 2007, and the collapse of Lehman Brothers in September 2008. Consequently, the risk premia on market-based sources of funding rose sharply, and money and capital market financing became significantly more expensive. A financial crisis ensued. This contrasts with a broadly stable financial system in 2022-23. Although there were increased risks to financial stability, especially in 2022, ¹⁸⁾ this was caused by higher uncertainty in the markets stemming from geopolitical tensions, in particular the war in Ukraine, as well as rising energy prices and persistent supply chain issues. In addition, rising inflation rates and subsequent interest rate hikes by the Eurosystem pushed up funding costs for enterprises and households, thereby contributing to tighter financial conditions. In spite of these challenges, supported by banks' robust capital and liquidity buffers, the financial system in the euro area proved resilient overall. ¹⁹⁾

¹⁸ See Deutsche Bundesbank (2022) and European Central Bank (2022).

¹⁹ See Deutsche Bundesbank (2023b) and European Central Bank (2023).

A further reason why the FCI was relatively high in the period prior to the financial crisis is that the yield curve at that time was still sloping upwards, whereas it had already inverted again in 2023 (see Chart 2.13). In 2008, the market was not expecting the sudden interest rate cuts that were soon necessitated by the financial crisis. This explains why long-term interest rates were higher than short-term interest rates. By contrast, in 2023, following extensive monetary policy tightening measures, the market quickly began to expect interest rates to be cut, which meant that long-term interest rates had already begun to decline again at the end of 2023. This is because the level that key interest rates had reached seemed comparatively high, as the period of low interest rates was still prominent in people's minds. This was due to the extensive monetary policy measures implemented in the previous decade.

The most recent increase in the FCI occurred after a sustained period of negative interest rates, which started from a historically low level. In the aftermath of the financial crisis, there was a long-term decline in the general level of interest rates. Faced with the financial crisis and the European sovereign debt crisis, the ECB Governing Council cut key interest rates to unprecedented levels. Low rates of inflation in the years that followed prompted the ECB Governing Council to adopt further monetary policy measures. Thus, the interest rate on the deposit facility was lowered into negative territory in June 2014. Short-term market interest rates subsequently also dropped to negative levels. In addition, the ECB Governing Council adopted further

non-standard measures, such as the APP, with the aim of flattening the yield curve at

Deutsche Bundesbank

the long end, too. The ECB Governing Council also implemented measures to directly reduce banks' funding costs. These included TLTRO I, TLTRO II and TLTRO III. These measures led to the FCI declining to one unprecedented low after another amid a general decline in interest rates and yields. It fell to its lowest level to date in August 2021. This means that its starting level at the end of 2021 was also significantly lower than it was when monetary policy tightening began in 2005.

The lower general level of interest rates was reflected in all components of the FCI; however, interest rates on the deposits of other financial corporations and the yields on securitised liabilities saw a particularly sharp decline. That said, interest rates on deposits of households and non-financial corporations in the euro area were also noticeably lower at the end of 2021 than they had been at the beginning of the financial crisis, hovering at historically low levels. The decline in the aggregated deposit interest rate was also intensified by volumes shifting towards overnight deposits, which are generally remunerated at lower interest rates than time deposits.

The FCI also fell between 2008 and 2023 as a result of volume shifts triggered by monetary policy and regulatory measures, and consisted of reallocations away from market-based funding towards deposit-based funding. The supplementary information on the impact of monetary policy and regulatory measures on banks' funding mix shows that the share of deposits in the financing mix increased between 2008 and 2023 for a number of reasons. These include the non-standard monetary policy measures such as the APP, the PEPP and the TLTROs. The purchase of assets by the Eurosystem and the increase in lending that the measures were intended to achieve coincided with a rise in deposits. This growth in deposits was further supported by the fact that, unlike alternative forms of investment, bank deposits rarely bore negative interest, which made them more attractive for depositors. From a regulatory point of view, the implementation of mandatory liquidity requirements (liquidity coverage ratio(LCR) and net stable funding ratio (NSFR)) provided incentives for banks to increase the share of deposits of households and small and medium-sized enterprises in their financing mix. This is because these kinds of deposits are regarded as a fairly stable source of funding and are therefore accorded a privileged status when calculating liquidity ratios. The volume shifts in the financing mix towards deposits came mainly at the expense of securitised liabilities, which, up until the onset of the financial crisis, had a much greater weighting in the financing mix than they did in recent years. Their greater weight at the time was the result of a wave of liberalisation, the core elements of which strengthened the significance of capital market financing via bank bonds and institutional investors, above all for large banks and Landesbanken. After the financial crisis, the non-standard monetary policy measures also served to make capital market financing less attractive. More recently, however, regulatory requirements for loss-absorbing capacity and the scaling back of non-standard monetary policy measures have once again boosted the significance of securitised liabilities in the financing mix.

Supplementary information

The impact of monetary policy and regulatory measures on banks' funding mix

Compared with 2008, the level of funding costs – as measured by the financing cost indicator(FCI) of banks in Germany depicted in Chart 2.11 – was lower in 2023, also due to volume shifts in the funding mix of banks. From 2008 to 2023, the funding mix underwent a significant shift – away from market-based financing and towards customer deposits (see the centre of Chart 2.11). This supplementary information addresses the extent to which monetary policy and regulatory measures have contributed to the change in the financing structure of banks.

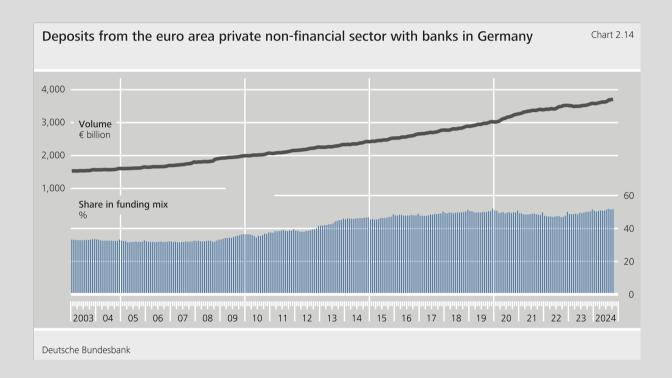

Customer deposits held with banks grew markedly from 2008 onwards as a result of an increasingly expansionary monetary policy stance and its positive impact on lending (see Chart 2.14). Expansionary monetary policy measures – such as the declining key interest rates in the euro area between 2008 and 2019 – generally affect the volume of deposits at banks: if the central bank reduces its policy rates, banks' financing costs generally fall. Banks usually pass on reduced financing costs to their customers by lowering the interest rates on the loans they offer. ¹⁾ Demand for loans usually rises as lending rates fall, and lending increases. ²⁾ As banks create new book money in the form of overnight deposits when lending, a rise in lending is accompanied by growth in deposits. ³⁾ Non-conventional monetary policy measures, such as

¹ See Deutsche Bundesbank (2023a).

² For further information on transmission channels, see Deutsche Bundesbank (2017), pp. 27f.

³ See Deutsche Bundesbank (2017).

asset purchase programmes and longer-term refinancing operations, can also cause deposits to grow owing to an increase in banks' lending. When assets are purchased by the central bank, this may result in an immediate increase in deposits, because if the central bank purchases a security from a domestic non-bank, payment of the purchase price is usually settled via the bank managing the seller's account. The seller's deposits increase as a result of the purchase amount being credited to the seller's account. ⁴⁾

The de facto zero lower bound for overnight deposits, especially for households, also contributed to the increase in deposits. For instance, the Eurosystem's policy rate cuts and asset purchase programmes led to a decline in the general level of interest rates and yields. ⁵⁾ However, for households' overnight deposits, which constitute the largest share of bank deposits in the private non-financial sector, the decline in interest rates effectively came to a halt at the zero lower bound. This was because banks were reluctant to pass on negative interest rates to their depositors, particularly in the case of households. ⁶⁾ As a result, the yield spread narrowed between investments that

⁴ The reduction in investment opportunities caused by the purchase programmes is also likely to have contributed to the increase in deposits. With the Eurosystem purchasing large volumes of bonds from 2015 onwards, this meant they were no longer available to households on the market. As a result, they had fewer alternative forms of investment available to them and this, too, is likely to have boosted the rise in deposits.

⁵ See Deutsche Bundesbank (2017), p. 28.

⁶ See Bittner et al. (2022), Heider et al. (2019), Kerbl and Sigmund (2016) and Deutsche Bundesbank (2020).

usually have higher returns and bank deposits. Accordingly, it became more attractive for households to hold their financial resources in overnight bank deposits. On top of this, households have repeatedly been exposed to high uncertainty since 2008. Households' already relatively high risk aversion is likely to have increased since price swings in capital markets picked up during the global financial crisis and the European sovereign debt crisis. ⁷⁾ In addition, uncertainty about economic developments during the pandemic and after the outbreak of the Russian war of aggression against Ukraine grew. ⁸⁾ For these reasons, too, it became more attractive for households to park freedup funds in liquid investments or forms of investment perceived to be low-risk, such as bank deposits. ⁹⁾ ¹⁰⁾ However, the defacto zero lower bound for deposits meant that these deposits, which had been comparatively favourable at other times, were now a relatively expensive source of financing for banks. As the period of negative interest rates grew longer, some banks therefore tried to limit inflows of deposits by applying negative interest rates to deposits above a certain amount, for example.

Changes to liquidity regulations are also likely to have contributed to deposit growth in the funding mix of banks. The financial crisis showed that short-term large-volume deposits by institutional investors ¹¹⁾ may be withdrawn quickly by depositors in periods of heightened uncertainty. This can lead to liquidity shortages among banks. As a result, supervisors and regulators set themselves the goal of making banks' funding less vulnerable to unexpected liquidity outflows and ensuring banks' solvency at all times. Minimum requirements were therefore introduced as part of liquidity regulation. One of these requirements involved a liquidity buffer that banks are required to hold for periods of stress (liquidity coverage ratio, LCR), whilst another concerned the ratio between the maturity structures of lending and deposit business (net stable funding ratio, NSFR). The deposits of households and small and medium-sized enterprises are privileged when calculating the LCR and the NSFR. This is because, unlike deposits from larger enterprises, individual deposits are often amounts that are fully covered by the statutory deposit insurance scheme. They are therefore considered to be a relatively

⁷ See Deutsche Bundesbank (2015b), pp. 26-31.

⁸ The share of currency and deposits in households' total financial assets rose in the wake of the financial crisis and stood almost continuously above 50% between September 2014 and June 2021. Households built up currency and deposits mainly at the expense of any debt securities they held.

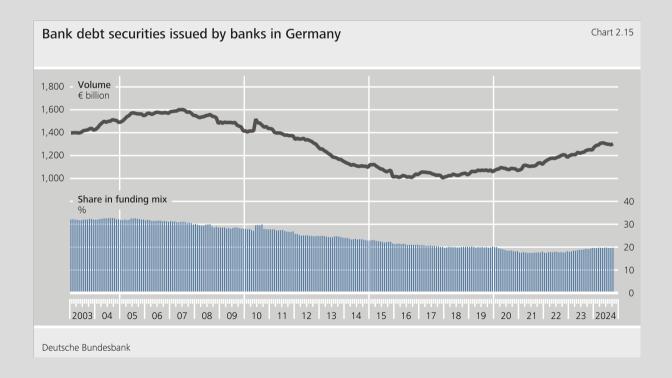

⁹ Government bonds, which households had traditionally invested in frequently in the past, were then purchased and held on a larger scale by the Eurosystem.

¹⁰ Uncertainty also led non-financial corporations to step up their overnight deposits. However, their share in the volume of deposits in the private non-financial sector rose from 11% to 16% between September 2008 and October 2023, whereas households' share of overnight deposits increased from 26% to 49% over the same period.

¹¹ These deposits are generally not covered by the deposit insurance scheme.

stable source of funding. ¹²⁾ Taken by itself, this provides incentives for banks to acquire or hold such deposits.

The volume shifts in the funding mix towards deposits were mainly at the expense of securitised liabilities: these had had a significantly greater weight in the funding mix in the years up to the outbreak of the financial crisis than more recently. The blue bars in Chart 2.15 show that the share of bank debt securities stood at around 30 % between 2004 and 2008. This high level was the outcome of a wave of liberalisation, the core elements of which were the financial market promotion legislation of the 1990s. The Third Financial Market Promotion Act, in particular, paved the way for forms of financing such as bank debt securities, created a broader investor base and thereby strengthened the importance of capital market financing, especially for big banks and Landesbanken. As the chart shows, the outstanding volume of bank debt securities and their share in the funding mix are currently significantly lower than they were back then.

¹² Banks in the European Union have been required to comply with the LCR as a binding minimum level since 1 October 2015. The NSFR was introduced via amending Regulation 2019/876 (CRR II). It has been binding with a compliance level of 100 % since 28 June 2021.

¹³ See Deutsche Bundesbank (2015a), pp. 38ff.

The decline in the use of debt securities as a financing instrument was initially due to the deteriorating environment for issuing new instruments in the capital market following the financial crisis; later on, favourable funding opportunities via the central bank encouraged banks to move away from capital market financing. During the global financial crisis, investors were more focused on counterparty and liquidity risk than before. The increased risk perception resulted in higher risk premia and a deterioration in sales opportunities for unsecured bank bonds. The sharp rise in investors' risk appetite between the period of liberalisation and the financial crisis was also corrected. To ensure banks' access to funding despite a dysfunctional interbank market, in October 2008, the implementation of monetary policy switched to fixed rate tenders with full allotment and the main refinancing rate was reduced from 3.25 % to 0.25 % by May 2009. Compared with central bank financing, funding via the capital market became increasingly unattractive for banks. 14) This was reinforced from 2014 onwards by the three series of targeted longer-term refinancing operations (TLTROs) with maturities of up to four years, partly replacing the issuance of bank debt securities. ¹⁵⁾ Studies also suggest that, in the long term, monetary policy purchase programmes (in particular the three covered bond purchase programmes) adversely affected trading in covered bank bonds and thus their attractiveness as a source of financing for banks. 16)

By contrast, regulatory requirements to strengthen banks' loss absorbing capacity and the discontinuance of special monetary policy programmes have recently reinforced the importance of securitised liabilities in the funding mix. One of the responses to the financial crisis was to implement regulatory minimum requirements for loss-absorbing liabilities in order to bolster the credibility of a resolution regime. Following the requirements outlined in 2015-16 and the adoption of the banking package in 2019, ¹⁷⁾ the need for banks to return more strongly to financing through bank debt instruments became apparent. The fact that most of the third and final series of the Eurosystem's TLTROs were repaid in 2023 and 2024 is also likely to have

¹⁴ See Deutsche Bundesbank (2015a) and European Central Bank (2018), box 7.

¹⁵ Fudulache and Götz (2023) find that TLTROs caused banks in the euro area to substitute market funding.

¹⁶ See Weigerding (2023).

¹⁷ From the end of 2015 and the start of 2016, the requirements that could emerge from the TLAC standards for global systemically important banks and from MREL for European banks on an institution-specific basis were fleshed out (see Deutsche Bundesbank (2016)). As a result, banks signalled back in 2017 that they were again increasingly planning to issue uncovered/unsecured or even subordinated (i.e. non-preferred) bank debt securities. As the adoption of the banking package in 2019 grew closer, details on the eligibility of bank securities for inclusion in the loss-absorbing capacity were revised and subordination requirements were clarified (see Deutsche Bundesbank (2019)).

amplified this. ¹⁸⁾ According to the EBA Funding Plans of 2021 and 2023, banks therefore increasingly planned to carry out any refinancing that might become necessary using market-based financing instruments. The share of securitised liabilities in their funding mix has therefore risen again recently. However, the impact of the increase on FCI has so far been small. For example, the FCI would only be slightly lower if it were assumed that, all other things being equal, the volume of securitised liabilities had remained unchanged since 2022. ¹⁹⁾

¹⁸ See European Central Bank (2024).

¹⁹ The impact on the FCI would also be small if, instead of volume, the share of securitised liabilities in banks' funding mix were kept constant.

The reasons presented demonstrate that both price factors and factors affecting the structure of financing contributed to the difference in the level of the FCI in 2023 as compared to 2008. Consequently, it is not surprising that the FCI, measured in terms of the key interest rate level, is now significantly lower than in 2008. As a result of these wide-ranging structural changes, the FCI is not expected to fully return to the levels seen prior to the financial crisis.

6 Assessment of current situation and conclusion

Banks' funding costs have fallen only slightly so far from their peak in autumn 2023.

The monetary policy measures to cut interest rates adopted since June 2024 have merely had a small impact on the FCI. Although money market interest rates and yields on securitised liabilities have declined, the aggregated rate on deposits of the private non-financial sector in the euro area has changed little thus far. In a setting of declining key interest rates, banks are quicker to pass on rate cuts in their deposit business than they are to pass on key interest rate increases. ²⁰⁾ However, the effect of lowering interest rates is being counteracted by the sustained volume shift towards time deposits, which are remunerated at higher interest rates.

The increased share of deposits in the financing mix means that banks are able to exert a substantial influence on a larger portion of their funding costs. This potentially complicates any assessment of how monetary policy impulses are transmitted to banks' funding costs and ultimately to lending rates. However, Bundesbank analyses show that the transmission of changes in market interest rates to deposit rates is currently functioning in the same way that historical correlations in the period up to autumn 2023 would suggest.

In addition to deposits, financing in money and capital markets remains a key source of funding for banks, even if it is not currently as significant as it was in the period leading up to the financial crisis. The financial crisis showed that prices in money and capital markets can change quickly and significantly in the event of disruptions. For the most part, banks operate in these markets as rate takers, which means they exert little influence on prices. Nevertheless, price developments play an important role for the FCI because financing via money and capital markets continues to make up a material share of banks' financing mix. However, unlike prices, banks can, conversely, steer the volume of the debt securities that they issue comparatively well. The extent to which they are able or willing to make use of this source of financing depends on monetary policy, regulatory requirements and other structural factors. In

²⁰ For the asymmetry in the transmission of interest rates, see Deutsche Bundesbank (2023a), pp. 56 f.

recent years, banks have once again been raising more of their funding in the market. This development is likely to continue, given the final repayment in December 2024 of the funds taken up under TLTRO III and the scaling back of the monetary policy portfolio.

Developments in bank financing costs are of key importance for monetary policy because only a comprehensive picture can enable valid conclusions to be drawn about the transmission of monetary policy impulses. The FCI is a useful tool in this regard because it provides valuable supplementary information in a concise way. This is because it also takes shifts in banks' financing mix into account. These shifts can lead to a change in the cost of funding even if the prices of the individual sources of funding do not change.

German enterprises' profitability and financing in 2023 during the period of monetary policy tightening

Although the German economy was virtually stagnant, the profitability of non-financial corporations improved in 2023, with their pre-tax profit margin rising significantly to 5.3% from 4.2% in the previous year. This was mainly due to lower materials costs: in terms of volume, the fall in the prices for energy and intermediate inputs was greater than the rise in personnel expenses and interest costs. This was particularly true for energy companies, which benefited considerably from lower energy prices. On the income side, revenues rose only slightly in an environment of continued high inflation. Interest income and income from other long-term equity investments were the major contributors to profit margins, with the latter factor playing a particularly important role in transport equipment. Yet even without the one-off developments in the energy company and transport equipment sectors, the profit margin of non-financial enterprises remained high. With regard to their profitability, German enterprises seem to have coped well with the stagnation of economic activity in 2023.

Starting from a low level, corporate insolvencies rose sharply in 2023, mainly owing to the poor economic situation, catch-up and normalisation effects following the pandemic, and higher financing costs. Contact-intensive areas such as retail and the hotel and restaurant sector were particularly hard hit, as were sectors that tend to be more sensitive to interest rates, such as construction and real estate. The ICT sector and business-related services, which experienced exceptionally high demand during the pandemic, also contributed significantly to the increase.

In 2023, monetary policy tightening also pushed up the average interest rate on bank loans to non-financial corporations in Germany. Estimates using firm-level data from the Bundesbank show that contractionary monetary policy shocks already tend to dampen investment by non-financial corporations in Germany in the same year. The strongest impact is estimated to occur after about two years. Consistent with this, the interest rate reversal had left only moderate traces in enterprises' financial statements by the end of 2023.

Despite the weak state of the economy, enterprises remained well positioned in 2023 in terms of their liquidity and stability. The equity ratio rose again in 2023, having fallen over the previous three years, but remains below its pre-pandemic level. Enterprises' liquidity positions also remained favourable in 2023 and liquidity needs trended lower. The good profitability, solvency and liquidity position of enterprises in the non-financial corporate sector as a whole largely reflects developments across sectors.

The ongoing economic weakness is likely to continue to weigh on enterprises' business activity and thus their sales growth in 2024. At the same time, the pressure on costs is expected to

remain high due to persistently high financing and energy costs, as well as the sharp rise in wages. Cost factors are placing a particular strain on the competitive position of the industrial sector. On balance, this is likely to have a negative impact on profitability in some parts of the corporate sector in 2024.

1 Underlying trends

The German economy stagnated in 2023, while the tightening of monetary policy increased financing costs. Real GDP declined by a seasonally-adjusted 0.1 % compared to the previous year, due partly to the structural growth problems of the German economy and partly to weak domestic and foreign demand. Production remained well below medium-term aggregate production capacities. The rise in interest rates and high construction costs dampened investment demand. Gross fixed capital formation, especially in construction, fell. Private consumption also weakened after being a major driver of the economy in the two previous years. High inflation per se depressed real incomes and consumers' willingness to spend. Exports virtually stagnated in the face of weak global demand and a less favourable competitive environment, due in part to the appreciation of the euro. On the production side, the significant decline in the prices of imported intermediate inputs and commodities, especially in the energy sector, eased pressure on the cost structure in industry. Nevertheless, input prices remained above 2021 levels. The stable labour market helped employees to largely achieve their demands for real wage adjustments, increasing enterprises' personnel expenses. On the whole, therefore, the business environment remained difficult despite the fall in energy prices compared to the previous year.

Based on the annual financial statements available to date, pre-tax profit margins rose in 2023, from 4.2% in the previous year to 5.3%. ¹⁾ This was only just below the record figure from 2007. This positive development was due both to cost-side relief and to favourable developments on the income side. Material costs fell significantly due to the decline in prices of intermediate inputs, especially of energy. Despite a slight increase in interest costs, total costs fell significantly because lower material costs more than offset the higher personnel expenses. On the income side, revenues increased

¹ The analysis for 2023 is based on some 19,500 corporate annual financial statements, which were roughly extrapolated based on the evaluation of aggregate sales data from the business register.

slightly. In view of the continuing strong increases in selling prices, the price-adjusted revenues of enterprises are likely to have fallen, however. Nevertheless, interest income and income from other long-term equity investments contributed to an improvement in the earnings of enterprises compared to the previous year.

Developments in the automotive industry and amongst energy companies contributed to the increase in gross profit margins across the corporate sector. In contrast to 2022 and most likely also 2024, car sales were comparatively brisk in 2023. ²⁾ In addition, the automotive industry realised significant income from participating interests, mainly from abroad, possibly with the aim of smoothing fluctuations in profit in view of the annual financial statements. After recording some major losses in the previous year, energy companies reported their highest annual profits since records began in 1997, boosted by significantly lower material costs. The fact that sales declined less in comparison could indicate that price reductions on the purchasing side were not fully passed on to end customers. This would have significantly increased profit margins. ³⁾ Without the contribution of these two sectors, the gross profit margin would have increased by only 0.2 percentage point in 2023. ⁴⁾ But the gross profit margin in 2023 was high in a long-term comparison even without the contribution of these two sectors. With regard to their profitability, German enterprises seem to have coped well with the stagnation of economic activity in 2023.

² According to the Federal Statistical Office, both domestic and foreign sales in the automotive industry rose by around 11 % in 2023 over the previous year.

³ In addition, income increased due to the reversal of provisions for anticipated losses from pending transactions.

⁴ However, without these two sectors, it also fell less sharply in the previous year. In this calculation, the decline came to 0.5 instead of 0.9 percentage point and the gross profit margin to 5.3 % instead of 4.2 %.

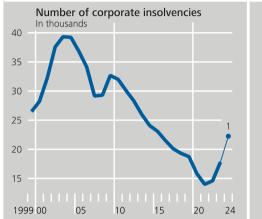

2 Development of corporate insolvencies

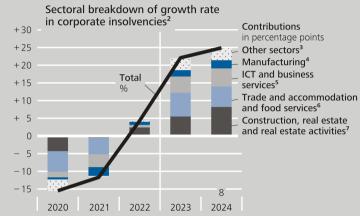

Corporate insolvencies rose sharply in 2023 year on year. The increase is due to the weak economic environment as well as to catch-up and normalisation effects in the wake of the pandemic. This applies in particular to the contact-intensive sectors of retail and the hotel and restaurant sector, which accounted for almost a third of the increase in corporate insolvencies in 2023. While economic activity in these sectors declined, in some cases significantly, during the coronavirus pandemic, corporate insolvencies in these industries fell sharply. The main factors in this were probably the suspension of the obligation to file for insolvency and extensive government support measures. 5) Despite this development, the share of persistently unprofitable enterprises in Germany did not increase during the pandemic (see the supplementary information entitled "Zombie firms in Germany during the COVID-19 pandemic"). Furthermore, by 2023, demand in sectors that had benefited from extremely strong demand during the pandemic is likely to have normalised. This is particularly true of information and communication services and business services, which together contributed slightly over one-fifth of the increase in corporate insolvencies in 2023. Moreover, the rise in corporate insolvencies can be partly attributed to the interest rate reversal in the summer of 2022. Evidence for this can be seen in the sharp increase in insolvencies in interest ratesensitive segments such as construction, real estate and other real estate-related sectors. Together, they accounted for a little over a quarter of the increase in corporate insolvencies. The manufacturing sector, in contrast, contributed comparatively little.

⁵ See Bundesbank (2021a).

Zombie firms in Germany during the COVID-19 pandemic

The phenomenon of zombie firms has once again come to the fore in view of weak **productivity growth in Germany.** In the literature, zombie firms are defined as firms that remain in the market despite having been unprofitable for several years. 1) They can benefit from the fact that banks grant them particularly favourable lending conditions in order to avoid realising losses from their business with them (something known as evergreening). 2) A sufficiently large number of unprofitable firms would impair aggregate productivity growth, as they tie economic resources – be it labour or capital input - inefficiently. The low interest rate environment during the years preceding the pandemic had already fuelled concerns that undercapitalised lenders would continue to finance this type of firm. Earlier Bundesbank analyses did not suggest an elevated share of zombie firms in Germany. 3) During the COVID-19 pandemic, German enterprises were granted extensive government support measures. This includes loans in which the development bankKreditanstalt für Wiederaufbau(KfW) assumed a large part of the default risk. In addition, the obligation to file for insolvency was temporarily suspended. These measures were intended to support firms that had suffered large losses in turnover and earnings as a result of the pandemic and the measures taken to contain it and to prevent fundamentally profitable firms from exiting the market. However, previously unprofitable enterprises may also have benefited from the support measures.

¹ The term zombie was first used to describe enterprises in the stagnating Japanese economy of the 1990s; see Caballero et al. (2008).

² For an overview of the literature, see Acharya et al. (2022).

³ See Deutsche Bundesbank (2017, 2020) and Bittner et al. (2021).

Sources: Annual financial statements of non-financial corporations (JANIS) as compiled by the Bundesbank, AnaCredit and Bundesbank calculations. The regressions control for enterprise size and sector classification. The estimated coefficients show the difference between zombie firms and other enterprises. **1** Estimates where the metric was regressed on a dummy variable for zombie firms. **2** Probit estimates where a dummy variable for COVID-19 assistance loans was regressed on a dummy variable for zombie firms. Only the years 2020 and 2021 were taken into consideration, as applications for the KfW loan programmes were generally only possible up until April 2022; see Federal Ministry for Economic Affairs and Climate Action (2022).

Deutsche Bundesbank

Developments in the share of persistently unprofitable firms in Germany can be estimated on the basis of the annual financial statements of non-financial corporations (JANIS) as compiled by the Bundesbank. ⁴⁾ In the JANIS dataset, these firms include – in line with the literature – any enterprises that have been unable to cover their interest expenses from their operating result for three consecutive years and are older than ten years. ⁵⁾ In addition, the definition used here allows firms to use additional financial income (including from equity interests in other enterprises) to cover interest expenses. ⁶⁾ This income is not insignificant for German enterprises.

The results show that the percentage of zombie firms in Germany did not increase during the COVID-19 pandemic. In addition, their share of sales declined during this

⁴ See Becker et al. (2024).

⁵ See Andrews and Petroulakis (2017) as well as McGowan et al. (2018).

⁶ This definition differs from the usual OECD definition; see Andrews and Petroulakis (2017). This approach is consistent with a recent study that suggests that the results could be distorted if additional income, such as financial revenues, is not taken into account. In particular, this increases the likelihood of enterprises being wrongly classified as zombie firms; see De Jonghe et al. (2024).

period. ⁷⁾ In contrast to earlier periods of weakness, such as the recession in the early 2000s or the economic and financial crisis of 2008-09, when the share of persistently unprofitable enterprises in Germany increased, it tended to decline during the pandemic. The fact that this share has dropped since 2020 – despite the pandemic and energy crisis – could be partly attributable to the conditions of the COVID-19 assistance measures. Some of these were linked to firms' profitability in the preceding years. ⁸⁾

Further analyses show whether persistently unprofitable firms benefited from particularly favourable financing conditions during the pandemic. This provides evidence of the extent to which these enterprises were kept alive by preferential treatment by banks (evergreening thesis). This also makes it possible to assess whether they benefited excessively from the COVID-19 assistance loans. To this end, financial characteristics of enterprises from the AnaCredit datasets up to 2022 are linked to enterprises' annual financial statements data. ⁹⁾ This allows us to analyse whether enterprises that were classified as zombie firms in 2019 were better off in terms of financial characteristics during the pandemic. ¹⁰⁾

Between 2019 and 2022, German credit institutions estimated the probability of loan default(PD) for persistently unprofitable firms to be higher than for other firms and demanded an appropriate interest rate premium. In the pre-crisis year of 2019, banks determined that zombie corporate borrowers were on average around 3 percentage points more likely to default on loans than other firms. This largely also applies to the pandemic period. ¹¹⁾ In other words, credit institutions were already aware of the risk of potential payment difficulties for these firms before – but also during – the pandemic. ¹²⁾ The associated higher interest rate premia reflect this. Even before the

⁷ According to international comparative studies, the share of zombie firms in Germany was very low between 1997 and 2021; see Albuquerque and Iyer (2023). Earlier analyses by the Bundesbank confirm that the share of zombie firms in Germany has tended to decline since the beginning of the 2010s; see Deutsche Bundesbank (2020).

⁸ For example, KfW express loans were subject to conditions relating to firms' profitability in the years prior to the pandemic. The emergency aid for small enterprises and the self-employed as well as the bridging aid were conditional on pandemic-related losses in turnover.

⁹ The analytical credit datasets, or AnaCredit, contain monthly information on individual bank loan agreements with legal persons and a lending volume of more than €25,000.

¹⁰ To this end, the AnaCredit financial characteristics are regressed to a dummy variable, which indicates whether an enterprise is a zombie firm as per the definition in 2019. The estimated coefficients show the difference between the categories of enterprises before (2019) and during the pandemic (2020 to 2022). The estimates are carried out separately for the years 2019, 2020, 2021 and 2022 and take into account sector classification and enterprise size.

¹¹ During the pandemic, zombie firms' PD decreased slightly compared with other firms. However, these changes cannot be clearly distinguished from one another statistically.

¹² In line with this, further results show that zombie firms experienced credit defaults, non-performing loans and payment arrears more frequently in relative terms between 2019 and 2022.

outbreak of the COVID-19 crisis, these firms had to pay an interest rate premium of around 30 basis points compared with other firms. The estimates suggest that this premium rose somewhat during the COVID-19 crisis – although this increase is in the range of statistical uncertainty. Overall, these results contradict the evergreening thesis and preferential treatment of zombie firms – including during the pandemic.

In addition, the probability of persistently unprofitable firms receiving a COVID-19 assistance loan was lower than for other firms. This is the result of additional estimates which match up with previous findings that these firms did not benefit any more than other enterprises from more favourable financing conditions during the pandemic. ¹³⁾

The analysis does not provide a comprehensive assessment of support programmes during the pandemic. First, it is based on only a small part of the support measures, namely the COVID-19 assistance loans. By contrast, the expansion of short-time working benefits and other extensive assistance to enterprises, such as direct transfers, say in the form of direct company subsidies for fixed costs, were not included in this analysis. Second, the share of zombie firms is only one of several criteria that should be used to assess the support measures. ¹⁴⁾

Looking at the results as a whole, there was no significant rise in persistently unprofitable firms in Germany during the pandemic. On the contrary, credit institutions appear to have been aware of the higher risk of lending to these corporate debtors – measured by PD and the interest rate – before and during the pandemic. These firms did not benefit excessively from the assistance loan programmes launched in the context of the pandemic either. ¹⁵⁾ It is therefore unlikely that zombie firms play a prominent role in the German economy's weak productivity growth which has been observed for some time now.

¹³ COVID-19 loans were, on average, larger in volume and had more favourable interest rates than normal loans.

¹⁴ Moreover, the Bundesbank's annual financial statements statistics are not a representative sample. Larger enterprises are overrepresented in the data, and sectoral coverage is uneven.

¹⁵ These results are largely in line with studies in France (seeCœuré(2021)), Italy (see Pelosi et al. (2021)), the United States (see Favara et al. (2021)) and the European Union (see Bighelli et al. (2022)).

In the first half of 2024, corporate insolvencies continued to rise sharply compared with the same period a year earlier. Extrapolated to the year, corporate insolvencies are expected to exceed pre-pandemic levels again in 2024 for the first time. Higher financing costs as well as catch-up and normalisation effects in the wake of the pandemic are having an impact this year, too. The fact that the German economy has not yet regained momentum is probably playing a certain role in the continued sharp rise in insolvencies.

3 The impact of monetary policy tightening on business investment and financing

The interest rate reversal in the euro area increased financing costs for German enterprises in 2023. This trend increased the cost of external financing for enterprises and raised debt servicing costs for new liabilities. In principle, this limits the scope for investment. The impact this has ultimately depends on the debt structure and the ability of enterprises to service interest costs or switch to other sources of financing. In addition to the impact on cash flow, an interest rate hike tends to dampen corporate investment by reducing the profitability of investment projects and making alternative investments more attractive, while falling asset prices also lower the collateral base for loans.

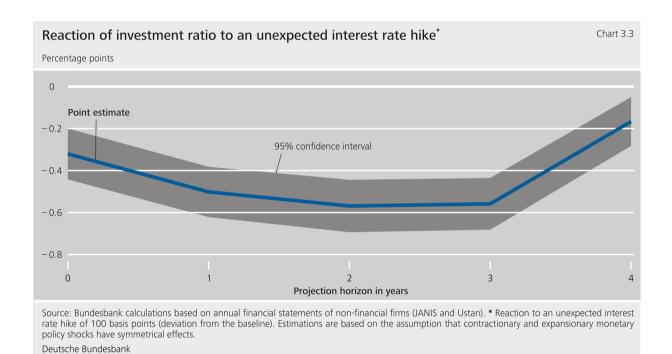

Estimates using Bundesbank firm-level data can provide insights into how the interest rate increases affected investment by German firms in the 2023 reporting year.

The study is based on extensive firm-level data by the Bundesbank since the 1970s, making it possible to analyse the effects of interest rate cycles over several decades. ⁶⁾ The local projections method is used to estimate the impact of monetary policy shocks on the investment ratio. ⁷⁾ The results show that, in the past, contractionary monetary policy shocks significantly dampened investment by non-financial corporations in Germany. For example, in the past an unexpected interest rate increase of 100 basis points reduced the investment ratio of German enterprises by 0.6 percentage point within two years. The effect could generally be seen in the year of the interest rate change and then intensified in subsequent years, before gradually subsiding after four years.

⁶ The data comprise over 160,000 observations from around 10,000 companies from 1973 to 2019 and are based on the Ustan and JANIS datasets. SeeBeckeret al. (2020, 2022, 2024).

⁷ In the first step, monetary policy shocks were identified using a Bayesian vector autoregressive model. See Kilian andLütkepohl(2017). In the second step, the estimate based on local projections takes into account both firm-specific and macroeconomic factors to determine the effect of unexpected interest rate changes on the firm-level indicators. The control variables include firm-specific characteristics such as the equity ratio and liquidity as well as macroeconomic variables such as the interbank interest rate and the output gap. See Jordà (2005) on the local projections method. See Alder et al. (2023) and Perez-Orive and Timmer (2023) for similar studies on France and the United States. The corporate investment ratio is defined here, as is common in the literature, as the change in tangible fixed assets (net investment) in relation to total assets in the previous year.

According to a rough calculation based on the estimated results, the latest interest rate hikes totalling 400 basis points between July 2022 and the end of 2023 may have reduced the investment ratio in the corporate sector by up to 2.4 percentage points. ⁸⁾ This assumes that these interest rate hikes were completely unexpected – which is unlikely to have been the case. Nevertheless, the estimates show that monetary policy tightening is likely to have a significant adverse effect on investment by the German corporate sector.

⁸ Given an average investment ratio of around 12% in the dataset this effect is quantitatively significant.

The results show that interest rate increases had a greater impact on the investment ratio than interest rate cuts. Looking at interest rate hikes separately from interest rate cuts in the estimates, an unexpected interest rate increase of, say, 100 basis points reduced German firms' investment ratio by around 1.3 percentage points on average after one year, ⁹⁾ while an interest rate cut of the same size only increased the investment ratio by 0.7 percentage point in the short term. ¹⁰⁾ This asymmetrical effect is presumably due to the fact that in some cases, higher interest rates can have the same effect as tighter credit restrictions for enterprises with weaker finances. One indicator of an enterprise's financial situation could be its equity base. This is because, according to the estimates, companies with a low equity ratio react more strongly to monetary policy shocks, while financially sounder companies are more resilient. ¹¹⁾ Additional analyses suggest that the asymmetrical effect has diminished over time, possibly because of the significant improvement in the capital base in the corporate sector over the last two decades. This may have reduced sensitivity to interest rate increases.

The interest rate reversal left only moderate traces in the annual financial statements available up to the end of 2023. Changes in interest rates are most likely to be reflected in companies' interest expenses and income, as well as in their liabilities. Accordingly, interest expenses did increase. The imputed interest rate, which is a measure of enterprises' actual financing costs, was only 3.6 %, placing it above the previous year's rate, but still below the level before 2016, with the exception of a one-off increase to 4.1 % in 2018. One reason for the comparatively moderate increase could be the slight rise in the discount rate for pension provisions, which reduced interest expenses somewhat. In previous years, the continuous decline of this rate, which is calculated as an average over the past ten years, had driven up expenses. In addition, many companies appear to have taken measures to limit their interest costs. For example, companies have scaled back long-term interest-bearing bank debt and are increasingly using customer advance payments as a source of financing. Companies also favoured financing with their own funds over using external funds.

⁹ Taken in isolation and in view of the current interest rate increase, roughly speaking, the investment ratio could be reduced even more strongly than the results without asymmetry suggest, i.e. by 5.2 percentage points.

¹⁰ For similar results, see Perez-Orive and Timmer (2023) and Kurt (forthcoming).

¹¹ See also Deutsche Bundesbank (2021b) and Perez-Orive and Timmer (2023).

In nominal terms, the investment ratio and the gross and net additions to tangible fixed assets continued to rise. This is also true for investments in subcategories such as land and buildings, technical equipment and machinery, and furniture and equipment. However, price effects in particular are likely to play a role here. According to the national accounts, gross fixed capital formation in the economy as a whole and investment in machinery and equipment fell after adjustment for inflation. Moreover, the effects of the interest rate reversal are not expected to be fully felt until two years after the interest rate hike, i.e. in the financial years 2024 and 2025, based on the estimates. It should be noted that interest rates on bank loans to non-financial corporations have fallen slightly again in 2024, which in itself is likely to mitigate the financial burden on companies somewhat.

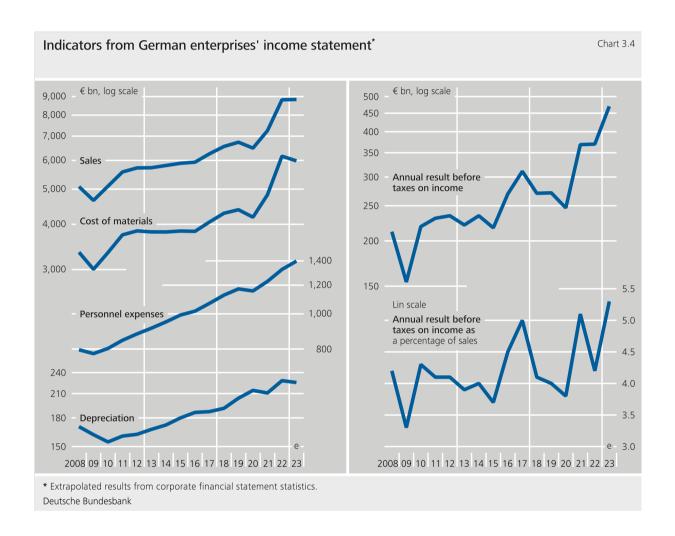

4 Sales and income

Unsurprisingly, given the challenging economic environment, the performance of non-financial corporations was weak in 2023. Sales in the non-financial corporate sector increased only slightly. The sales trend varied greatly by sector. For example, sales grew strongly in the hotel and restaurant sector (probably due in part to certain pandemic-related catch-up effects), among business service providers, in the motor vehicle trade, construction, manufacture of transport equipment and mechanical engineering. By contrast, energy-intensive industrial sectors such as the wood, paper and printing industry, the chemical and pharmaceutical industry and energy supply saw sales decline. 12) The decrease in sales in the energy-intensive manufacturing sector is probably also related to the fact that energy prices, although falling, were still high. For example, this could have led to parts of production being moved abroad or to a decline in shares of exports due to reduced competitiveness. Lower energy prices led to an immediate decline in sales in the energy supply business. The rise in sales in some parts of the services sector is thought to be mainly due to price effects given the environment of persistently high inflation. By contrast, interest income continued to grow strongly across all sectors as a result of the interest rate reversal. Income from other long-term equity investments rose significantly off the back of developments in the transport equipment and chemical and pharmaceutical industries.

Despite the generally weak performance, corporate profits rose sharply. This was mainly due to the fact that expenses were lower on average. This was because the cost of materials declined, partly as a result of falling prices for intermediate goods, especially energy. However, the drop in the cost of materials was limited to energy supply, energy-intensive manufacturing, and the transportation and storage sector. In the remaining economic sectors, costs merely increased less than in the previous year. In sectors with high sales growth, the cost of materials increased correspondingly.

¹² Here, the energy-intensive manufacturing sector comprises the wood, paper and printing industries, the chemical and pharmaceutical industries, the rubber, plastics and ceramics industries, and the metal industry. Owing to the small number of enterprises, the coke and refined petroleum products industry, which is also energy-intensive, is not reported separately in the annual financial statements statistics. It cannot therefore be included in the energy-intensive manufacturing sector.

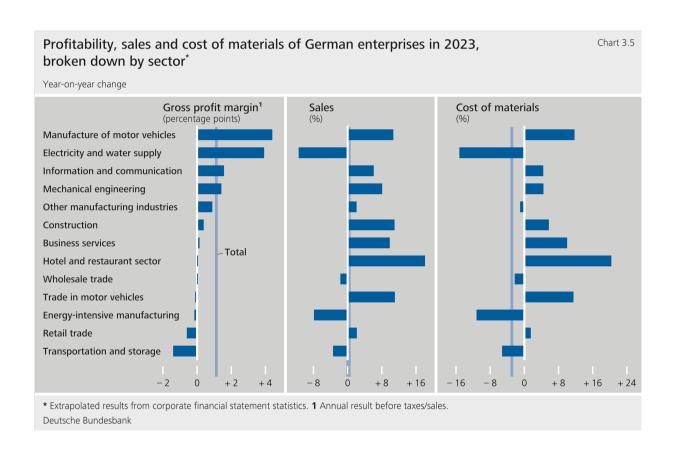

There were further sharp increases (in most sectors) in personnel expenses due to significant wage increases and in interest expenses due to the interest rate reversal. One exception to this is the chemical and pharmaceutical industry, where both cost items fell. ¹³⁾

From a sectoral perspective, too, profitability remained robust in 2023. Despite falling sales, the profitability of energy-intensive manufacturing industries declined only slightly because of reduced costs. Although gross profit margins fell in the wood, paper and printing industries, for example, they were still above the historical average. In the other energy-intensive industrial sectors, profitability remained close to the long-term average. Across all sectors, the highest increases in gross profit margin were

¹³ The decline in personnel expenses is mainly due to lower expenses for company pensions (including an adjustment of the pension trend due to lower inflation expectations) at large enterprises. On the one hand, the sharp fall in liabilities played a role in the decline in interest expense. On the other, the interest expense in 2022 was exceptionally high by historical standards.

recorded by the manufacture of transport equipment, energy supply and electrical engineering. The sectors in which the increase in profitability was primarily due to growth in income rather than reduced pressure on expenses included – in addition to transport equipment and the rest of the manufacturing sector – the information and communication sector, the mechanical engineering sector and the construction sector ¹⁴).

¹⁴ The rest of the manufacturing sector mainly comprises the electrical industry, the food industry and the clothing industry.

5 Balance sheet developments

The growth in corporate assets weakened in 2023 in view of the more subdued economic situation. Growth in non-financial corporations' total assets was much lower on average than in the two previous years. Enterprises used the additional funds largely for the formation of non-financial assets, while the acquisition of financial assets was weak. The share of financial assets thus decreased, as in the previous year, due mainly to the decline in total receivables. While long-term receivables continued to rise, short-term receivables, which account for a much larger share of the balance sheet, decreased. By contrast, other long-term equity investments rose sharply, as in the two previous years. In 2023, efforts to conserve liquidity were no longer a major factor for most enterprises, as liquid funds in the form of cash and bank deposits were reduced. The liquidity needs of most sectors changed only slightly. The strong increase in non-financial assets in large parts of the corporate sector was due in roughly equal measure to tangible fixed assets and inventories. The increase in tangible fixed assets was higher than in the previous year, while intangible fixed assets barely increased. However, it is not immediately obvious from corporate financial statements that many enterprises are looking into the use of artificial intelligence. This is easier to identify using more granular datasets (see the supplementary information on "The adoption and objectives of artificial intelligence in German firms"). However, the increase in inventories was not as high as in the previous year, partly due to muted price developments and stagnating sales. Moreover, supply chain disruptions were resolved in 2023, which reduced the need for increased inventory.

Supplementary information

The adoption and objectives of artificial intelligence in German firms

The digital transformation has the potential to radically alter business and working life. The use of artificial intelligence(AI) especially could invigorate aggregate productivity growth in Germany, which has long been sluggish. (1) Generative AI is seen as the major technological advance in this regard. Because it can handle complex tasks that were previously considered exclusively executable by humans, it holds the promise of substantial productivity gains. In contrast to earlier technological innovations that automated routine tasks, generative AI is able to create content such as text or images by itself, which could potentially make human work significantly more efficient. (2)

A representative online survey of just under 7,000 German firms conducted by the Bundesbank provides detailed insights into the use of digital technologies in 2024 as well as the reasons motivating their adoption. The analysis focuses on four key technologies: predictive and generative AI, cloud computing, infrastructure technologies for integrating work and/or production processes, and robotics. Until now, there has been very little reliable information on the adoption and use of digital technologies in the German corporate sector. 4)

In the current early phase of AI adoption, two-fifths of firms are already engaging with the technology. Notably, in the second quarter of 2024, 43 % of the surveyed enterprises were using predictive or generative AI at least experimentally or were

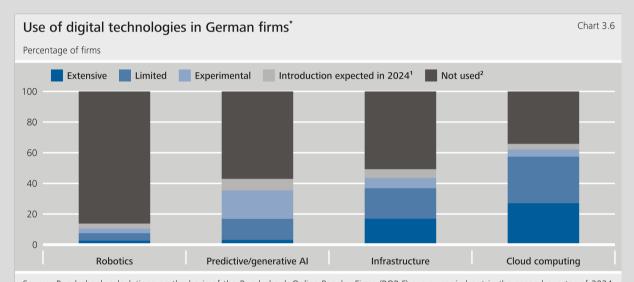

¹ For details on the general significance of digitalisation for productivity growth, seeDeutsche Bundesbank (2023).

² See also Elondou et al. (2023).

³ For more information on the Bundesbank Online Panel – Firms (BOP-F) survey, see Bundesbank (2021c) and Boddin and Köhler (2023).

⁴ Exceptions include results of surveys conducted by the Federal Statistical Office and the ifo Institute. See Destatis (2024) and Schaller et al. (2023).

planning to introduce it before the end of 2024. Only 3 % were making extensive use of it, which is probably because the technology is so new. Most firms using AI were therefore doing so experimentally (19 %). A slightly smaller number of firms had already taken things a step further and were using it to a limited extent (14 %). A further 8 % do plan to implement it by the end of 2024. The majority of firms are not yet using AI and are not intending to introduce it before the end of 2024. Cloud computing (66 %) and infrastructure technologies (49 %), on the other hand, are more widespread. Robotics (14 %) are deployed chiefly in industrial sectors.

Source: Bundesbank calculations on the basis of the Bundesbank Online Panel – Firms (BOP-F) survey carried out in the second quarter of 2024. * Firms from all economic sectors. Question: To what extent does your enterprise currently use the following digital technologies? Weighted results based on 6,885 (robotics), 6,904 (Al), 6,902 (infrastructure for integrating work and/or production processes) and 6,906 (cloud computing) responses. 1 Currently not in use, but implementation planned before the end of 2024. 2 Currently not in use, no implementation planned before the end of 2024

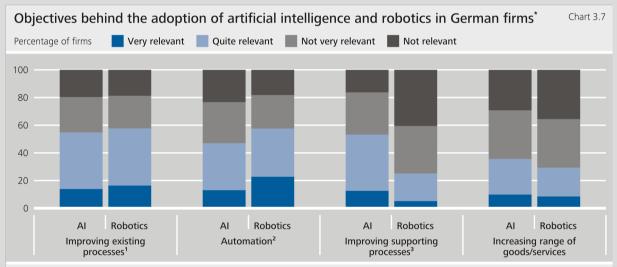

Deutsche Bundesbank

The use of predictive and generative AI varies widely depending on sector and firm size. It is particularly prevalent in sectors characterised by data-driven processes and digital interaction, such as information, communication and finance. By contrast, it figures less frequently in economic sectors where tasks are of a more manual or interactive nature, such as healthcare, hospitality and transport. Large firms are driving the adoption of AI: 78 % of enterprises with turnovers of more than €229 million use AI or are planning to introduce it, compared with just 37 % of firms with turnovers under €1 million. According to an OECD study, high costs, a lack of technical expertise and

⁵ Surveys by the ifo Institute have found that the proportion of firms using AI grew by 14 percentage points to 27 % between 2023 and 2024. See Kerkhof et al. (2024). In a similar vein, generative AI appears to be being adopted exceptionally rapidly in the United States, with uptake progressing at a much faster pace than previous rollouts of new technologies such as the PC or internet. See Bick et al. (2024).

lower perceived benefit are key barriers for smaller firms. ⁶⁾ The same pattern is also evident with other digital technologies, such as cloud computing and robotics.

According to the findings, firms primarily use robotics to automate tasks, whilst AI is mainly being used to improve supporting processes. A key objective for both technologies is the optimisation of methods or processes that are already automated (AI: 55%; robotics: 58%). The automation of existing activities is particularly important for robotics (58%), but does also play a significant role for AI (47%). AI is also important for improving supporting processes such as in the areas of human resources or marketing (53%), whereas robotics are naturally less applicable in these areas (25%). Expanding the range of goods and services on offer is a lower-priority objective in the case of both technologies (AI: 36%; robotics: 29%).

Source: Bundesbank calculations on the basis of the Bundesbank Online Panel – Firms (BOP-F) survey carried out in the second quarter of 2024. * Question: How relevant are the following objectives to your enterprise with regard to adopting artificial intelligence/robotics? Weighted results based on 3,181 to 3,187 firms (predictive and/or generative artificial intelligence) and 1,305 to 1,307 firms (robotics) who were making extensive, limited or experimental use of the technology in question or were planning to adopt it by the end of 2024. 1 Improving already automated work methods and/or processes. 2 Automating activities previously performed by employees. 3 Human resources, marketing, etc.

Deutsche Bundesbank

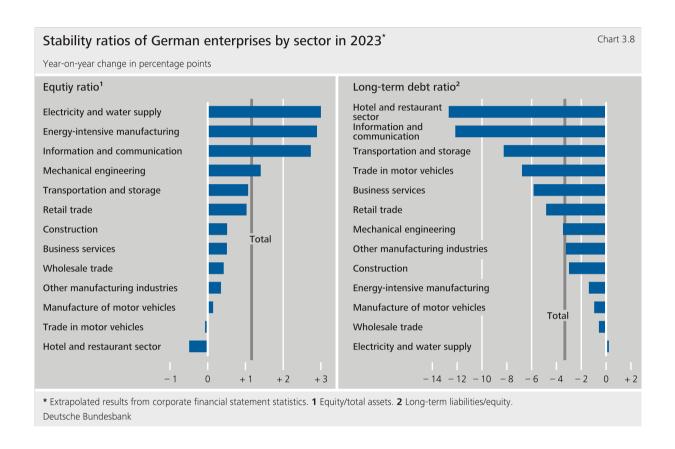

The effects of generative AI on the labour market and productivity are likely to be very different from those of robotics. While the survey results do not provide direct insights into the productivity or labour market impacts of AI or robotics, they do suggest – in line with the literature – that robotics are predominantly being used to automate manual activities. In contrast, generative AI comprehensively transforms work processes and could significantly boost productivity, especially in supporting

⁶ See Lane et al. (2023).

functions. Widespread use of generative AI could thus provide positive impetus for aggregate potential growth. Estimates of AI's effect on productivity are, however, fraught with uncertainty. Empirical studies show a wide range of outcomes, ranging from modest effects to substantial aggregate productivity gains. ⁷⁾ What is sure, is that improved digital infrastructure and targeted training measures are essential to fully realising the growth potential of this technology.

⁷ For studies on productivity gains in specific activities, see Noy and Zhang (2023), Peng et al. (2023) and Dell'Acqua et al. (2023). On the basis of a back-of-the-envelope calculation, Acemoglu (2024) estimates that the impact o annual labour productivity growth in the United States will be fairly modest, amounting to about 0.1 % over the next ten years. A similar analysis byBergeaud(2024) under different assumptions shows slightly larger effects for the euro area. In contrast to this, other studies point towards very sizeable effects; see Briggs and Kodani (2023) and Aghion and Bunel (2024).

The capital base of enterprises improved on average in 2023. On the revenue side, most of the additional corporate funds were sourced internally, with a significant share coming from retained earnings. In contrast to equity, liabilities and provisions increased only slightly. The noticeable increase in the equity ratio thus roughly offset the decline from the previous year. The equity ratio rose in almost all sectors.

Liabilities shifted proportionately from long-term to short-term on balance, as in the two previous years. Short-term liabilities rose only slightly on average in 2023. Although advance payments received on account of orders and short-term liabilities to banks increased sharply, the reduction in trade payables and other liabilities had an offsetting effect. At the same time, enterprises reduced their long-term liabilities by decreasing their long-term liabilities to banks. ¹⁵⁾ In contrast to the three previous years, provisions also increased only slightly. The rising discount rate resulting from the interest rate reversal may also have provided relief with respect to pension provisions.

¹⁵ The minimal increase in additional liabilities was the main reason for the low contribution of external financing to corporate funding in 2023.

Supplementary information

Profitability and financial position of German listed groups in 2023 and an outlook for 2024

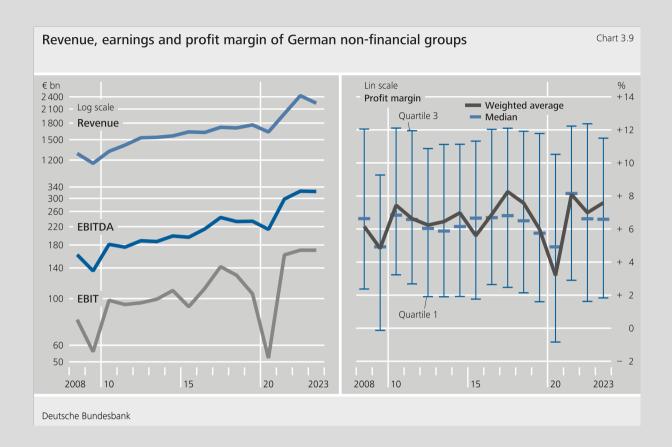

German listed groups' revenue fell by 8 % in 2023, following strong growth in the two preceding years. ¹⁾ Operating income before (EBITDA) and after (EBIT) depreciation and amortisation stagnated. As a result, the profit margin increased by 0.7 percentage point to 7.6 %. ²⁾ It is thus above its mean since 2007 of 6.6 %.

The increase seen in groups' profit margin is not broad based. The profit margin rose, especially in the case of large energy groups. Measured in terms of EBIT, their earnings situation in 2022 was still considerably affected by the additional costs of purchases to make up for the absence of commodity supplies from Russia and unfavourable valuation effects of derivatives for hedging against commodity price risks. These burdens ceased to exist in 2023, meaning that energy groups improved their profits significantly despite a decline in revenue. Excluding energy groups, the profit margin in the production sector fell by 1 percentage point to 7.6 %. The chemical industry, in particular, suffered from energy prices that were still higher than in 2019. These prices weighed on their competitiveness and it is likely that relocations of production abroad took place. Moreover, impairments were necessary due to higher capital costs and deteriorating business prospects. The profit margin in the services sector fell by 1 percentage point to 10.1 %. This was chiefly attributable to the drop in the profit margin seen in the logistics sector when taking the exceptionally high level in 2022 as a starting point. Average freight rates fell in 2023 as a result of weak demand and the normalisation of supply chains, which had a detrimental effect on the profitability of the logis-

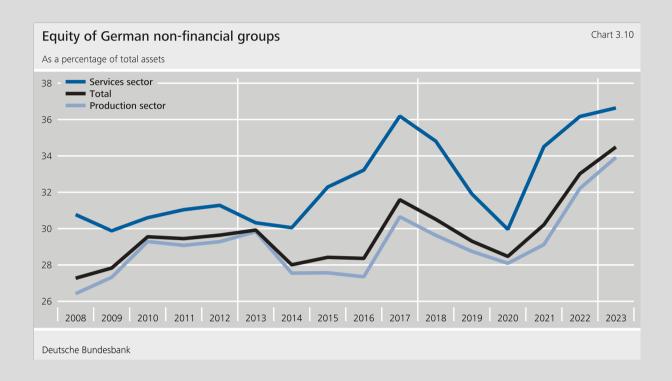

¹ The reporting sample for the consolidated financial statements statistics comprises around 220 non-financial groups admitted for trading on the Prime Standard segment of the Frankfurt Stock Exchange (excluding real estate activities) that publish quarterly or half-yearly IFRS consolidated financial statements and make a meaning ful contribution to value added in Germany. Groups are allocated to the production sector or services sector based on the main focus of their economic activity.

² The rates of change for revenue, earnings before interest, taxes, depreciation and amortisation (EBITDA), earnings before interest and taxes (EBIT) and the profit margin (ratio of EBIT to revenue) are published with reporting and consolidation basis adjustments, albeit not the figures in euro billions or the weighted average profit margin.

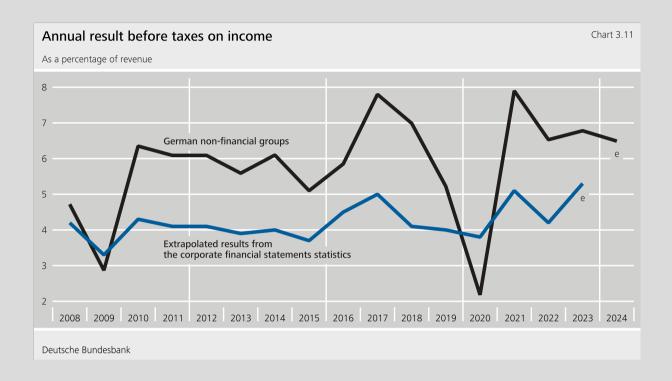

tics sector. The profit margin of groups in the rest of the services sector did not improve either.

The balance sheet saw groups' assets contract by 3 % in 2023. This was mainly due to the significant loss in the value of energy groups' derivative assets. Lower commodity prices had an impact here. As a result, long-term assets fell by 1 % and short-term assets by 7 % in the reporting sample. In the case of the latter, the exceptionally high profit distribution of one single logistics group was another factor behind this development.

On the financing side, equity was up slightly by 1% in 2023. The retention of profits played a key role in this context. High spending on pension provisions and currency translation differences had a negative impact. Buy-backs also weighed on equity. Debt fell by 5%, mainly due to the valuation of energy groups' derivatives positions, as was the case for assets. Overall, the leverage ratio declined, and the capital ratio increased by 1.5 percentage point to 34.5%. In the production sector, it rose from 32.2% to 33.9%. The ratio grew more moderately in the services sector, rising 0.4 percentage point to 36.6%. The lower capital ratio of the production sector compared with the services sector was once again attributable to automobile manufacturers' financing business in 2023. In some cases, this has a major impact on the financial structure at group level. Excluding the segments in automobile groups with a focus on financial services business, the capital ratio of the production sector increased from 36.8% to 39.8% in 2023.

For 2024, there appears to be a moderate decline in revenue and a significant drop in pre-tax profits according to groups' interim financial statements that are currently available and have been evaluated. Groups' profit margin is likely to decline somewhat as a result. This probably partly reflects the current earnings trends of domestic companies in the corporate financial statements statistics. ³⁾ Viewed at the sector level of groups in the year to date, the picture that emerges is mixed. The services sector has increased its revenue and profits slightly. In the production sector, by contrast, automobile manufacturers, in particular, have recorded a decrease in revenue and strong earnings declines due to a weakness in sales as well as restructuring and transformation expenses. In addition, falling electricity and gas prices have led to a decline in energy groups' revenue, while their pre-tax profits have not reached the high level achieved in the previous year.

³ Alongside the stronger impact of global economic developments on consolidated financial statements, the metrics derived from the financial statements are materially shaped by differences between the accounting standards applied (German GAAP for corporate financial statement statistics (single-entity), IFRS for consolidated financial statement statistics).

6 Conclusion

Despite the weak development of the economy and higher financing costs, non-financial corporations performed well in 2023 in terms of their earnings and financing conditions. Energy-intensive enterprises continued to be negatively affected, probably in connection with the rise in energy prices, which worsened their competitive position. However, the corporate sector as a whole was able to increase its profitability compared to the previous year despite higher interest and personnel expenses. The fact that enterprises are offsetting lost revenue with cost savings also played a role, as sales growth was weak in 2023, and inflation remained high.

Stability metrics also improved. In addition to the gross profit margin and the capital base, enterprises' liquidity levels was also very good and long-term liabilities continued to fall.

2024 will be another challenging year for enterprises. The ongoing economic weakness is likely to weigh on enterprises' business activity and thus their sales growth in 2024. At the same time, the pressure on costs is expected to remain high due to persistently high financing and energy costs, as well as the sharp rise in wages. These pressures can also be seen in the increased number of corporate insolvencies, which are expected to exceed pre-pandemic levels again for the first time in 2024. On the one hand, cyclical stress factors are creating headwinds for enterprises. On the other, German firms are facing structural challenges posed by a shortage of skilled workers due to demographic factors, the green and digital transition of the economy, and the changed global economic environment. On balance, this is likely to weigh on profitability in some parts of the corporate sector, such as the manufacturing industry, and dampen profitability in the corporate sector as a whole in 2024.

Long series of extrapolated results of the corporate financial statement statistics are available online at www.bundesbank.de.

of paper issued by euro area MFIs. **9** Including national banknotes still in circulation. **10** The German contributions to the Eurosystem's monetary aggregates should on no account be interpreted as national monetary aggregates and are therefore not comparable with the erstwhile German money stocks M1, M2 or M3. **11** The

difference between the volume of euro banknotes actually issued by the Bundesbank and the amount disclosed in accordance with the accounting regime chosen by the Eurosystem (see also footnote 2 on banknote circulation in Table III.2).

euro banknotes put into circulation by the Bundesbank in accordance with the accounting regime chosen by the Eurosystem (see also footnote 2 on banknote circulation in Table III.2). The volume of currency actually put into circulation by the

Bundesbank can be calculated by adding to this total the item "Intra-Eurosystem liability/claim related to banknote issue" (see "Other liability items"). 5 Excluding central governments' deposits. 6 In Germany, only savings deposits.

^{*} Monetary financial institutions (MFIs) comprise banks (including building and loan associations), money market funds, and the European Central Bank and national central banks (the Eurosystem). 1 Source: ECB. 2 In Germany, only savings deposits. 3 Excluding holdings of MFIs; for the German contribution, excluding German MFIs' portfolios of securities issued by MFIs in the euro area. 4 In Germany, bank debt securities with maturities of up to one year are classed as money market paper.

⁵ Excluding liabilities arising from securities issued. **6** After deduction of inter-MFI participations. **7** The German contributions to the Eurosystem's monetary aggregates should on no account be interpreted as national monetary aggregates and are therefore not comparable with the erstwhile German money stocks M1, M2 or M3. B Including DEM banknotes still in circulation (see also footnote 4 on p. 10*). **9** For the German contribution, the difference between the volume of euro banknotes

Discrepancies may arise from rounding. * The banking system's liquidity position is defined as the current account holdings in euro of euro area credit institutions with the Eurosystem. Amounts are derived from the consolidated financial statement of the Eurosystem and the financial statement of the Bundesbank. 1 Figures are daily averages for the reserve maintenance period ending in the month indicated. Following the changeover in the frequency of Governing Council monetary policy meetings to a six-week cycle, a reserve maintenance period no longer ends in every month. No figures

are available in such cases. **2** Source: ECB. **3** Includes liquidity provided under the Eurosystem's asset purchase programmes. **4** From August 2009 includes liquidity absorbed as a result of the Eurosystem's foreign exchange swap operations. **5** From 2002 euro banknotes and other banknotes which have been issued by the national central banks of the Eurosystem and which are still in circulation. In accordance with the accounting procedure chosen by the Eurosystem for the issue of euro banknotes, a share of 8% of the total value of the euro banknotes in circulation is

allocated to the ECB on a monthly basis. The counterpart of this adjustment is shown under "Other factors". The remaining 92% of the value of the euro banknotes in circulation is allocated, likewise on a monthly basis, to the NCBs, with each NCB showing in its balance sheet the share of the euro banknotes issued corresponding to ts paid-up share in the ECB's capital. The difference between the value of the euro banknotes allocated to an NCB and the value of the euro banknotes which that NCB has put into circulation is likewise shown under "Other factors". From 2003 euro

banknotes only. **6** Remaining items in the consolidated financial statement of the Eurosystem and the financial statement of the Bundesbank. **7** Equal to the difference between the sum of liquidity-pro viding factors and the sum of liquidity-absorbing factors. **8** Calculated as the sum of the "Deposit facility", "Banknotes in circulation" and "Credit institutions' current account balances".

^{*} The consolidated financial statement of the Eurosystem comprises the financial statement of the European Central Bank (ECB) and the financial statements of the national central banks of the euro area Member States (NCBs). The balance sheet items for foreign currency, securities, gold and financial instruments are valued at market

rates at the end of the quarrter. 1 In accordance with the accounting procedure chosen by the Eurosystem for the issue of euro banknotes, a share of 8% of the total value of the euro banknotes in circulation is allocated to the ECB on a monthy basis. The counterpart of this adjustment is disclosed as an "Intra-Eurosystem liability related to

19°

euro banknote issue". The remaining 92% of the value of the euro banknotes in circulation is allocated, likewise on an monthly basis, to the NCBs, with each NCB showing in its balance sheet the share of the euro banknotes issued corresponding to its paid-up share in the ECB's capital. The difference between the value of the euro

banknotes allocated to the NCB according to the aforementioned accounting procedure and the value of euro banknotes put into circulation is also disclosed as an "Intra-Eurosystem claim/liability related to banknote issue". **2** For the Deutsche Bundesbank: including DEM banknotes still in circulation. **3** Source: ECB.

 $^{^\}star$ This table serves to supplement the "Overall monetary survey" in Section II. Unlike the other tables in Section IV, this table includes - in addition to the figures reported by

banks (including building and loan associations) - data from money market funds. ${\bf 1}$ See footnote 1 in Table IV.2. ${\bf 2}$ Excluding deposits of central governments.

3 In Germany, debt securities with maturities of up to one year are classed as money market paper; up to the January 2002 Monthly Report they were published together

with money market fund shares. 4 Statistical breaks have been eliminated from the flow figures (see also footnote * in Table II.1).

^{*} Assets and liabilities of monetary financial institutions (MFIs) in Germany. The assets and liabilities of foreign branches, of money market funds (which are also classified as MFIs) and of the Bundesbank are not included. For the definitions of the respective items, see the footnotes to Table IV.3. 1 Owing to the Act Modernising Accounting Law (Gesetz zur Modernisierung des Bilanzrechts) of 25 May 2009, derivative financial instruments in the trading portfolio (trading portfolio derivatives) within the meaning of

Section 340e (3) sentence 1 of the German Commercial Code (Handelsgesetzbuch) read in conjunction with Section 35 (1) number 1a of the Credit Institution Accounting Regulation (Verordnung über die Rechnungslegung der Kreditinstitute) are classified under "Other assets and liabilities" as of the December 2010 reporting date. Trading portfolio derivatives are listed separately in the Statistical Series Banking statistics, in Tables I.1 to I.3. 2 For building and loan associations: including deposits under savings

¹ The reserve maintenance period starts on the settlement day of the main refinancing operation immediately following the meeting of the Governing Council of the ECB for which the discussion on the monetary policy stance is scheduled. 2 Article 5 of the Regulation (EU) 2021/378 of the European Central Bank on the application of minimum reserve requirements (excluding liabilities to which a reserve ratio of 0% applies, pursuant to Article 6(1)(a)). 3 Amount after applying the reserve ratio to the reserve base. The reserve ratio for liabilities with agreed maturities of up to two years was 2%

between 1 January 1999 and 17 January 2012. Since 18 January 2012, it has stood at 1%. 4 Article 6(2) of the Regulation (EU) 2021/378 of the European Central Bank on the application of minimum reserve requirements. 5 Average credit balances of credit institutions at national central banks. 6 Average credit balances less required reserves after deduction of the lump-sum allowance. 7 Required reserves after deduction of the lump-sum allowance.

End of month 2023 Oct. 2024 Jan

> The interest rate statistics gathered on a harmonised basis in the euro area from January 2003 are collected in Germany on a sample basis. The MFI interest rate statistics are based on the interest rates applied by MFIs and the related volumes of euro-denominated deposits and loans to households and non-financial corporations domiciled in the euro area. The household sector comprises individuals (including sole proprietors) and non-profit institutions serving households. Non-financial corporations include all enterprises other than insurance corporations, banks and other financial include all enterprises order than insurance corporations, banks and other financial institutions. The most recent figures are in all cases to be regarded as provisional. Subsequent revisions appearing in the following Monthly Report are not specially marked. Further information on the MFI interest rate statistics can be found on the Bundesbank's website (Statistics/Money and capital markets/Interest rates and yields/Interest rates on deposits and loans). • The statistics on outstanding amounts are collected at the end of the month. • The effective interest rates are calculated either as

annualised agreed interest rates or as narrowly defined effective rates. Both calculation methods cover all interest payments on deposits and loans but not any other related charges which may occur for enquiries, administration, preparation of the documents, guarantees and credit insurance. 2 Data based on monthly balance sheet statistics.

3 Secured and unsecured loans for home purchase, including building and home improvements; including loans granted by building and loan associations and intering credit as well as transpired learn greated by the proportion great in their own pares. credits as well as transmitted loans granted by the reporting agents in their own name and for their own account. 4 Loans for consumption are defined as loans granted for the purpose of personal use in the consumption of goods and services. 5 For the purpose of these statistics, other loans are loans granted for other purposes such as the consumption of the purpose such as the purpose of the purpose of the purpose of the purpose such as the purpose of the business, debt consolidation, education, etc. 6 Including overdrafts (see also footnotes 12 to 14 on p. 47)

For footnotes * and 1 to 6, see p. 44°. For footnote x see p. 47°. + For deposits with an agreed maturity and all loans excluding revolving loans and overdrafts, credit card debt: new business covers all new agreements between households or non-financial corporations and the bank. The interest rates are calculated as volume-weighted average rates of all new agreements concluded during the reporting month. For overnight deposits, deposits redeemable at notice, revolving loans and overdrafts, credit card debt: new business is collected in the same way as outstanding amounts for the sake of simplicity. This means that all outstanding deposit and lending business at

the end of the month has to be incorporated in the calculation of average rates of interest. **7** Estimated. The volume of new business is extrapolated to form the underlying total using a grossing-up procedure. **8** Including non-financial corporations' deposits; including fidelity and growth premiums. **9** Excluding overdrafts. **10** Annual percentage rate of charge, which contains other related charges which may occur for enquiries, administration, preparation of the documents, guarantees and credit insurance.

For footnotes * and 1 to 6, see p. 44•. For footnotes + and 7 to 10, see p. 45•, 11 For the purposes of the interest rate statistics, a loan is considered to be secured if collateral (amongst others financial collateral, real estate collateral, debt securities) in at least the same value as the loan amount has been posted, pledged or assigned. 12 Including revolving loans which have all the following features: (a) the borrower may use or withdraw the funds to a pre-approved credit limit without giving prior notice to the lender; (b) the amount of available credit can increase and decrease as funds are borrowed and repaid; (c) the loan may be used repeatedly; (d) there is no obligation of regular repayment of funds. 13 Overdrafts are defined as debit balances

on current accounts. They include all bank overdrafts regardless of whether they are within or beyond the limits agreed between customers and the bank. 14 Including convenience and extended credit card debt. Convenience credit is defined as the credit granted at an interest rate of 0% in the period between payment transactions effected with the card during one billing cycle and the date at which the debt balances from this specific billing cycle become due. 15 The amount category refers to the single loan transaction considered as new business. x Dominated by the business of one or two banks. Therefore, the value cannot be published due to confidentiality.

Sources: The calculations for the insurance sectors are based on supervisory data according to Solvency I and II and for pension funds on IORP supervisory data and own data collections. 1 Accounts receivable to monoteary financial institutions, including registered bonds, borrower's note loans and registered Pfandbriefe. 2 Including deposits retained on assumed reinsurance as well as registered bonds, borrower's note loans and registered Pfandbriefe. 3 Including reinsurance recoverables and claims of

pension funds on pension managers. **4** Not including the reinsurance business conducted by primary insurers, which is included there. **5** The term "pension funds" refers to the institutional sector "pension funds" of the European System of Accounts. Pension funds thus comprise company pension schemes and occupational pension schemes for the self-employed. Social security funds are not included.

Sources: The calculations for the insurance sectors are based on supervisory data according to Solvency I and II and for pension funds on IORP supervisory data and own data collections. 1 Including deposits retained on ceded business as well as registered bonds, borrower's note loans and registered Pfandbriefe. 2 Including claims of pension funds on pension managers and entitlements to non-pension benefits. 3 Technical reserves "life" taking account of transitional measures. Health insurance is also included

in the "non-life insurance" sector. **4** Not including the reinsurance business conducted by primary insurers, which is included there. **5** Valuation at book values. The term "pension funds" refers to the institutional sector "pension funds" of the European System of Accounts. Pension funds thus comprise company pension schemes and occupational pension schemes for the self-employed. Social security funds are not included. **6** Own funds correspond to the sum of "Net worth" and "Shares and other equity".

¹ Bearer debt securities with maximum maturities according to the terms of issue of over 4 years. Structured debt securities, debt securities with unscheduled redemption, zero coupon bonds, floating rate notes and bonds not denominated in Euro are not included. Group yields for the various categories of securities are weighted by the amounts outstanding of the debt securities included in the calculation. Monthly figures

are calculated on the basis of the yields on all the business days in a month. The annual figures are the unweighted means of the monthly figures. Adjustment of the scope of securities included on 1 May 2020. **2** Only debt securities eligible as underlying instruments for futures contracts; calculated as unweighted averages.

Source: Bundesbank calculations based on Federal Statistical Office data. 1 Annual figures based on the quarterly figures of the Federal Statistical Office, core budgets and off-budget entities which are assigned to the general government sector. 2 The annual figures do not tally with the sum of the quarterly figures, as the latter are all provisional. The quarterly figures for some insurance sectors are estimated. 3 The development of the types of expenditure recorded here is influenced in part by statistical

changeovers. 4 Including discrepancies in clearing transactions between central, state and local government. 5 On the revenue side, this contains proceeds booked as disposals of equity interests and as loan repayments. On the expenditure side, this contains the acquisition of equity interests and loans granted. 6 Excluding central government liquidity assistance to the Federal Employment Agency.

Source: Federal Ministry of Finance and Bundesbank calculations. 1 This total, unlike that in Table X. 5, does not include the receipts from the equalisation of burdens levies, local business tax (less local business tax transfers to central and state government), real property taxes and other local government taxes, or the balance of untransferred tax shares. 2 Respective percentage share of central, state and local government in revenue: wage tax and assessed income tax 42.5:42.5:15, corporation tax and non-assessed taxes on earnings 50:50:-, final withholding tax on interest income and capital gains, non-assessed taxes on earnings 44:44:12. 3 After deducting child benefits and subsidies for supplementary private pension plans. 4 After deducting employee

refunds and research grants. **5** After deducting research grants. **6** Final withholding tax on interest income and capital gains, non-assessed taxes on earnings. **7** The allocation of revenue to central, state and local government, which is adjusted at more regular intervals, is regulated in Section 1 of the Revenue Adjustment Act. Respective percentage share of central, state and local government in revenue for 2023: 47.5:49.7:2.8. The EU share is deducted from central government's share. **8** Respective percentage share of central and state government for 2023: 41.4:58.6. **9** For the breakdown, see Table X. 7.

Sources: Federal Statistical Office; Federal Employment Agency. * Annual and quarterly figures: averages; calculated by the Bundesbank; deviations from the official figures are due to rounding. 1 Workplace concept; averages. 2 Monthly figures: end of month. 3 Number within a given month. 4 Mid-month level. 5 Relative to the total civilina labour force. 6 Excluding government-assisted forms of employment and seasonal jobs, including jobs located abroad. 7 Statistical break due to late recording of unemployed persons in the legal category of the Second Book of the Social Security Code (SGB II).

8 Unadjusted figures estimated by the Federal Employment Agency. In 2022 and 2023, the estimated values for Germany deviated from the final data by a maximum of 0.1% for employees subject to social contributions, by a maximum of 0.5% for persons solely in jobs exempt from social contributions, and by a maximum of 61.3% for cyclically induced short-time work. **9** From May 2024, calculated on the basis of new labour force figures. **10** Initial preliminary estimate by the Federal Statistical Office.

^{*} Non-financial groups admitted to the Prime Standard segment of the Frankfurt Stock Exchange which publish IFRS consolidated financial statements on a quarterly or half-yearly basis and make a noteworthy contribution to value added in Germany. In some cases revised. Excluding groups engaged in real estate activities. 1 Earnings before interest, taxes, depreciation and amortisation. 2 Earnings before interest and taxes. 3 Quantile data are based on the groups' unweighted return on sales. 4 Annual figures

do not always match the sum of the two half-year figures. See Quality report on consolidated financial statement statistics, p. 3. **5** Adjusted for substantial changes in the basis of consolidation of large groups and in the reporting sample. See Quality report on consolidated financial statement statistics, p. 6. 6 From 2018 onwards: significant changes in IFRS standards, impairing comparability with previous periods. **7** Including groups in agriculture and forestry.

^{*} Assets and liabilities vis-à-vis all countries within and outside the euro area. Up to December 2000 the levels at the end of each quarter are shown, owing to revaluations, at market prices; within each quarter, however, the levels are computed on the basis of cumulative transaction values. From January 2001 all end-of-month levels are valued at market prices. 1 Mainly net claims on TARGET2 balances (acc. to the respective country designation), since November 2000 also balances with non-euro area central banks

within the ESCB. 2 Mainly long-term debt securities from issuers within the euro area. 3 Including estimates of currency in circulation abroad. 4 See Deutsche Bundesbank, Monthly Report, October 2014, p. 22. 5 Difference between External assets and External liabilities. 6 Euro opening balance sheet of the Bundesbank as at 1 January

8. External positions of enterprises *

^{*} The effective exchange rate corresponds to the weighted external value of the currency concerned. The method of calculating the indicators of the German economy's price competitiveness is consistent with the procedure to compute the effective exchange rates of the euro. A decline in the figures implies an increase in competitiveness. The weights are based on trade in manufactured goods and services. For more detailed information on methodology and weighting scale, see the website of the Deutsche Bundesbank (https://www.bundesbank.de/content/796162). 1 The calculations are based on the weighted averages of the changes in the bilateral exchange rates of the euro vis-à-vis the currencies of the following 18 countries: Australia, Bulgaria, Canada, China, Czechia, Denmark, Hong Kong, Hungary, Japan, Norway, Poland, Romania, Singapore, South Korea, Sweden, Switzerland, the United Kingdom and the United States. Where current price and wage indices were not available, estimates were used.

2 Includes countries belonging to the extended EER group of trading partners (fixed composition) and additionally the following 23 countries: Algeria, Argentina, Brazil, Chile, Colombia, Iceland, India, Indonesia, Israel, Malaysia, Mexico, Morocco, New Zealand, Peru, Philippines, the Russian Federation, Saudi Arabia, South Africa, Taiwan,

Thailand, Turkey, Ukraine and United Arab Emirates. The ECB has suspended the publication and calculation of the euro foreign exchange reference rate against Russian rouble with effect from March 2, 2022 until further notice. For the calculation of effective exchange rates, an indicative rate is used for the Russian Federation from that date. It is calculated from the daily RUB/USD rates determined by the Bank of Russia in conjunction with the respective ECB's euro foreign exchange reference rate to the US dollar. 3 Annual and quarterly averages. 4 Euro area countries (from 2001 including Greece, from 2007 including Slovenia, from 2008 including Cyprus and Malta, from 2009 including Slovakia, from 2011 including Estonia, from 2014 including Latvia, from 2015 including Lithuania, from 2023 including Croatia) as well as Canada, Denmark, Japan, Norway, Sweden, Switzerland, the United Kingdom and the United States. 5 Euro area countries (current composition) and countries belonging to the extended EER group of trading partners (fixed comosition). 6 Euro area countries (current composition) and countries belonging to the broad EER group of trading partners (fixed comosition).
